Abstract

Are regulatory intervention measures successful in alleviating a financial crisis? What works? Using the Japanese banking crisis as our laboratory, we utilize a novel, *hand-gathered* bank-specific database to provide an empirical answer to the above questions. Our results indicate that while substantial risk-based capital infusions (similar to the 2009 stress tests in US) are successful in stimulating aggregate lending, blanket infusions (similar to TARP infusions of October 2008) are not effective. Regulatory forbearance, manifest in changes in accounting valuation procedures (similar to the regulation FAS 157-4 in US) while failing to stimulate aggregate lending, has an allocative impact. Drawing parallels to the US public policy programs implemented to alleviate the current crisis, we argue that policies must be substantial in size and risk-targeted to be effective.

Regulatory Remedies for Banking Crises: Lessons from Japan

Periodically, banking panics lead to financial crises as witnessed by the global financial meltdown of 2007-2009, which was triggered by the bursting of the US housing price bubble and the resulting increase in mortgage delinquencies. Inevitably, a crisis leads to calls for regulatory policy changes that are designed to return the financial system to health. The 2007-2009 global financial crisis has witnessed a quick succession of regulatory experiments designed to restart global financial markets and recapitalize a banking system that had been depleted by loan losses and deteriorating asset values.

Many economists and financial pundits have drawn the parallel between the 2007-2009 crisis and Japan's lost decade of the 1990s, which was also triggered by the bursting of a real estate bubble and loan losses that depleted bank capital positions. In a pioneering study, Hoshi and Kashyap (2009) provide an in-depth analysis of the nature of the crises showing that the parallel between the two crises extends beyond their initial roots in the real estate sector.¹ There are public policy parallels in each government's reaction to the crisis. For example, in July 1999, Japan's Financial Supervisory Agency (currently known as the Financial Services Agency or FSA) required Japanese banks to conduct rigorous self-assessments of their assets for comparison across depository institutions. Similarly, in February 2009, the 19 largest US financial institutions were subjected to stringent stress test examinations in order to compare each bank's credit losses and capital positions under several economic scenarios.² Furthermore, both Japanese banks and US banks were offered governmental programs to replenish their capital positions. For example, in the US, the Troubled Asset Relief Program (TARP) was introduced in

¹ See Diamond, Kashyap and Rajan (2009) and Diamond and Rajan (2009) for a detailed analysis of the 2007-2009 US crisis. Additional literature in this area includes Reinhart and Rogoff (2008) who surveys financial crises throughout the world, and Yorulmazer (2009) who compares the US and the Swedish banking crises.

² Although originally designed to be worst-case scenario, during the months it took to implement the stress test, the economy deteriorated further so that the baseline scenario had already been breached by the date of publication of the results (March 7, 2009). For example, the consensus expected unemployment rate was 9.3% as of March 2009, rather than the 8.9% in the baseline scenario.

October 2008 to provide capital infusions to systemically important US banks.³ In Japan, public capital injections were designed to recapitalize the 19 systemically important Japanese banks, comprising the city banks, trust and long-term credit banks and 3 large regional banks.⁴

The objective of all of these public policy programs was to increase aggregate macroeconomic activity by stimulating bank-lending activity.

In this paper, we concentrate on three major public policy interventions undertaken in Japan during the acute phase of the Japanese banking crisis during 1997-1999 and draw parallels to public policy interventions in the US during 2008-2009.⁵ In particular, we utilize a unique hand gathered, bank specific database to empirically examine the lending activity of individual Japanese banks in reaction to each public policy stimulus program.

We first consider the government's provision of capital infusions to systemically important banks. In Japan, these public injections of capital took place in 1998, similar to the TARP capital infusions that were initiated in 2008 in the US. The similarity between these two policy programs was that in both cases the amount of each bank's capital infusion was unrelated to the bank's risk exposure or level of undercapitalization. Indeed, many adequately capitalized US banks were forced to take TARP funds in October 2008 in order to avoid transmitting a negative signal about those undercapitalized banks that had no choice but to participate in the program. Our results suggest that these across the board capital infusions were ineffective in stimulating aggregate lending activity during the Japanese crisis. One possible explanation is that the size of the blanket public injection program was insufficient to materially impact the recipient bank's insolvency risk. Philippon and Schnabl (2009) show that public capital

³ Bayazitova and Shivdasani (2009) show that TARP infusions had a positive impact on the equity valuations of recipient banks, particularly for those systemically important, troubled banks that were the first to receive capital infusions.

⁴ The Japanese capital injections in 1998 were mostly in the form of subordinated debt, and amounted to 1,816 billion yen, of which 321 billion was in the form of preferred stock. See Hoshi and Kashyap (2009). Later injections disbursed funds mostly in form of preferred stock. For example, for the 1999 capital injection, 7,459 billion yen were disbursed to 15 major banks, out of which 6, 159 billion yen were in the form of preferred stock. The TARP injections were in the form of preferred stock.

⁵ Although Japan's real estate bubble burst in the early 1990s, we consider public policy interventions beginning in 1997. Similarly, although the US banking crisis began in 2007, we consider policies undertaken in 2008 and 2009.

injections are successful in stimulating bank lending only if they decrease the bank's risk of insolvency.

The second public policy intervention arose out of the failure of the first. In contrast to the 1998 program of blanket capital infusions, Japanese government public injections of bank capital starting in 1999 were targeted to undercapitalized banks at risk of becoming insolvent. This ongoing program was more substantial in size and set the level of capital infusions equal to each bank's nonperforming loan losses. Total risk-based public capital infusions in 1999 totaled 74.593 trillion yen as compared to only 18.156 trillion yen in 1998. The risk-based capital infusion program in Japan can be compared to the US Supervisory Capital Assessment Program in 2009, which tested the adequacy of each bank's capital in order to determine the level of required capital infusions.⁶ Our empirical results suggest that risk-based capital infusions were effective in inducing Japanese banks to increase their lending activity. Therefore, although we find that direct public capital injections have a significantly positive effect on stimulating aggregate bank lending activity, the efficacy depends on how the public injections were conducted. The blanket public injection policy of 1998 failed to stimulate bank lending, whereas a stimulative effect was delivered by risk-based capital infusions starting in 1999 that mandated a rigorous examination of each bank's non-performing loans problems.⁷ Our results are consistent with those of Hoshi and Kashyap (2009) showing that risk in the Japanese banking system (measured using the "Japan premium" -- the Eurodollar Tokyo Interbank Borrowing Rate (TIBOR) minus 3-month LIBOR) increased in the wake of the 1998 public injection, but declined after the 1999 injections.

The third public policy intervention in Japan was the provision of regulatory capital forbearance through the introduction of a land revaluation windfall. On March

⁶ In the US, these capital infusions took two forms: public (the conversion of government-owned preferred stock into common stock to meet Tier 1 capital requirements) and private (the issuance of equity).

⁷ Peek and Rosengren (2001) also find that during periods of concrete action by the Japanese government, there is a reduction of the "Japan premium". In addition, Montgomery and Shimizutani (2009) find that the risk-based public injections were effective whereas the blanket infusions were not over the 1990-1999 period. Our results also highlight empirically the importance of systemic risk assessment as an important step in any policy to alleviate financial crises, as recommended by Acharya, Pedersen, Philippon and Richardson (2009). Gianetti and Simonov (2009) studying the impact of bank bailouts on clients of the banks reach a similar conclusion. However, it should be noted that Gianetti and Simonov (2009) conduct their exercise as an "event study" where each injection is represented as an event dummy in contrast to our study that includes actual figures for each injection and can therefore highlight the size effect on bank-lending explicitly.

31, 1998, the Diet (the Japanese parliament) passed the “Law Concerning the Revaluation of Land,” which allowed Japanese banks to count 45% of the unrealized capital gains on their real estate holdings as Tier 2 capital for the purposes of meeting their bank capital requirements.⁸ This revaluation essentially enabled Japanese banks to mark to market their real estate portfolio, which was previously held at book values that were decades old and lower than the prevailing land prices in Japan. Thus, all Japanese banks were allowed to increase the value of their assets by increasing the valuation of the land in their portfolios. The land revaluation allowance followed the format of an earlier equity revaluation allowance (introduced in 1986), which allowed Japanese banks to include 45% of the unrealized gains on securities as Tier 2 capital. However, the provision of equity revaluation allowance was granted only to those Japanese banks that had international operations. In contrast, because the land revaluation allowance was more broadly applicable (to all banks rather than just international banks for the equity revaluation allowance), our empirical analysis suggests that it had more of an impact on Japanese bank lending activity as compared to the equity revaluation allowance.

The 1998 land revaluation allowance (which was either positive or zero if there were no gains)⁹ essentially provided both domestic and international Japanese banks with an infusion of Tier 2 capital for regulatory capital purposes. That is, there was no change in the bank’s economic capital position, but regulators allowed banks to include previously ineligible asset values (land appreciation allowances) as Tier 2 capital for regulatory purposes. This policy was similar in nature to the infusion of capital in the form of supervisory goodwill that contributed to the thrift crisis in the US (see White (1991)). Land revaluation allowance thus represented an ongoing, permanent infusion of regulatory capital, since subsequent declines in land values did not have to be deducted from the bank’s regulatory capital position. Moreover, to the extent that Japanese banks held considerable land holdings that had been obtained upon real estate loan foreclosures,

⁸ The Basel Capital Accords specify that banks must hold both Tier 1 capital, comprised mostly of bank equity, and Tier 2 capital, comprised of preferred stock, long-term subordinated debt, up to 1.25% in the form of general loan loss provisions, and the revaluations permitted to Japanese banks.

⁹ Banks had the discretion to choose whether or not to declare an allowance for land revaluation. Therefore, there were no instances of negative land revaluation allowances as of the regulatory date of revaluation.

the land revaluation law substantially enhanced the ability of Japanese banks to meet their Tier 2 capital requirements.

Parallel to the land revaluation allowance policy's accounting rule changes, on April 9, 2009, the US Financial Accounting Standards Board published FAS 157-4: *"Determining Fair Value When the Volume and Level of Activity for the Asset or Liability Have Significantly Decreased and Identifying Transactions That Are Not Orderly"*, which allowed banks to avoid market value accounting "when the volume or level of activity for the asset or liability have significantly decreased and identifying transactions are not orderly." This permitted US banks to avoid capital charges that would have resulted from valuing their financial assets and liabilities at the low prices prevalent during the crisis period. Our results indicate that this form of forbearance that propped up regulatory (but not economic) capital levels was ineffective in stimulating Japanese bank lending during the crisis. Instead of increasing total lending, this policy only had allocative effects. That is, Japanese bank lending shifted from residential real estate to non-residential real estate lending without an aggregate increase in total lending.

An issue hitherto not addressed in Japanese banking literature is the behavioral response of Japanese banks in the wake of the crisis that intensified during the period of regulatory interventions. In Japan, some banks responded to their capital constraints by switching their charter designations so as to ease regulatory capital requirements.¹⁰ During the Japanese banking crisis, 62 banks switched their charters from international to domestic only, thereby cutting their capital requirements in half, as well as retaining access to the land revaluation allowance.¹¹ Given the timing of majority of these switches (1998-1999), it becomes imperative for any study on the efficacy of regulatory intervention measures to take into account the impact of this shift in operational jurisdiction of banks on bank lending behavior. In this paper, we address this issue by first establishing that regulatory capital requirements can be a binding constraint on bank behavior. In particular, we analyze the charter switching decision and show that banks with marginal shortfalls in regulatory capital switched charters so as to take advantage of

¹⁰ As will be discussed in Section 2, Japanese banks with only domestic operations had a 4% capital requirement in contrast to the 8% requirement for international banks.

¹¹ There was only one bank, Yasuda Trust, that switched (in March 2003) in the opposite direction, from domestic to international, but we could not obtain sufficient data about the bank's portfolio to include it in our sample.

the reduction in their capital requirements. Moreover, the restricted applicability of the equity revaluation allowance (i.e., only banks with international operations were eligible) reduced the tendency of banks to switch charters from international to domestic only.

We next establish that the empirical results pertaining to the impact on bank lending behavior of regulatory intervention measures are robust to a two-stage analysis that controls for the endogeneity of the switching decision. To account for the possible endogeneity in the charter switching decision, we first employ a probit regression to estimate the probability that a bank would switch its charter. We find that it was the bigger, better-capitalized banks that had an increased probability to switch their charter from international to domestic operations, whereas direct public injections dissuaded a bank from switching its charter.¹² We also control for the ability of the bank to take advantage of the mark-to-market accounting changes through both the equity and land revaluation allowances. Since the allowances effectively increased the bank's Tier 2 capital, there were limitations on the ability of the bank to benefit from the Tier 2 regulatory capital forbearance. Bank capital requirements limit the amount of eligible Tier 2 capital to be less than Tier 1 capital. Thus, Tier 2 capital must comprise less than half of a bank's total capital requirements. Our probit regression analysis shows that banks with more unused Tier 2 capacity were more likely to switch their charter so as to increase their regulatory capital position. Further, our two-stage analysis is consistent with our results that risk-based capital infusions were effective in stimulating bank-lending activity during the Japanese banking crisis, whereas across the board capital infusions had no impact on aggregate bank lending. Regulatory forbearance, through suspension of mark-to-market accounting requirements via the land revaluation allowance, had only an allocative, not an aggregate impact on bank lending activity.

The paper proceeds as follows. Section 2 provides a brief review of the literature and a description of Japanese bank capital regulations and policies during the 1980s-2000s. Section 3 describes our hand-collected database and provides descriptive statistics. In Section 4, we present the results of our baseline model as well as

¹² Kroszner and Strahan (1996) find that thinly capitalized thrifts were most likely to switch from a mutual to a stock charter in order to obtain access to private capital. This counterintuitive result obtains from their finding that thrift regulators allowed mutual-to-stock conversions of weak thrifts (and subsequently large dividend payouts) because they did not have funds to bail them out.

endogenize the process of Japanese bank switching of charter and examine the two-stage regression results. We next discuss some robustness checks. The paper concludes in Section 5.

2. Japanese Regulatory Policies Over the 1980-2000 Period

Prior to the adoption of the Basel Accords, the regulatory capital requirement in Japan was set at 4%, as calculated by capital divided by total assets less specific bad debt reserves. However, Japan had a two-tiered system that continues to this day.¹³ That is, Japanese banks that operate overseas branches were allowed to include 70% of unrealized gains on securities in their capital calculation, but were required to meet a 6% capital ratio.^{14, 15} In contrast, domestic banks with no international branches could not include their unrealized gains on securities as capital, but were required to meet only a 4% ratio.

Upon the agreement to adopt the Basel Accords in 1988, a four-year transitional period was initiated.¹⁶ Basel I was fully implemented in Japan as of March 1993, with the exception that the Japan's Ministry of Finance permitted only Japanese banks with international operations to include 45% of the unrealized gains on securities as Tier 2 capital (in a line item known as the equity revaluation allowance). Unrealized losses on securities and cross holdings of stocks of other financial institutions were deducted from Tier 1 capital for all Japanese banks (both with and without international branches). Capital requirements were calculated on a consolidated basis only. Most importantly, however, the 8% Basel capital requirement was not levied on domestic Japanese banks without international operations. These banks retained the 4% non-risk based requirement.

¹³ Japan's economy is largely bank-based. Kang and Stulz (2000) find that strong reliance on bank financing and the lack of alternative sources of funds in Japan contributed to the decline in firm value displayed by the loss of more than half of equity value for the typical firm on the Tokyo Stock Exchange during 1990 to 1993.

¹⁴ Specific loan loss reserves, which write off specific individual loans, were excluded from both the numerator and the denominator of the capital ratio (though general provisions for loan losses and reserves were included in the numerator) for Japanese banks with international branches. Moreover, cross holdings of stocks were not deducted from the numerator.

¹⁵ According to Himino (2005), Japan's international (city) banks would have been unable to meet the 6% capital requirement if they could not utilize reserves from their unrealized gains on securities (also known as hidden reserves).

¹⁶ During 1988 to 1990, Japanese banks were required to keep their risk-based capital levels at levels no lower than those as of the end of fiscal year 1987. During 1990-1992, the requirement was increased to 7.25%, and to 8% when Basel I took full effect in March 1993.

In 1993, the Japanese financial system was reformed so as to allow banks to underwrite corporate bonds through bank-owned subsidiaries.¹⁷ The Financial System Reform Act of 1992 (which took effect in April 1993) was designed to promote competition in Japanese financial markets. Takaoka and McKenzie (2006) find that the law achieved this result since underwriting commissions and yield spreads on corporate bonds fell dramatically with bank entry into the underwriting business. The two major reforms were: (1) permitting the consolidation of banking and securities firms through subsidiaries, and (2) allowing securities firms to participate in the market for securitizations.¹⁸

Hoshi and Kashyap (2009) date the start of Japan's financial crisis to the loan loss problems at the housing loan institutions (*jusen*) that were created in the 1970s. In 1991, non-performing loans at the *jusen* totaled 38% of their total loans.¹⁹ The Ministry of Finance and the large Japanese banks made several rescue attempts to prop up the insolvent *jusen*, all of which were unsuccessful, and by 1995, the *jusen* were liquidated. At around the same time, in response to the continuing banking crisis, the 10 million yen deposit insurance cap was eliminated and full deposit insurance was extended to all deposits for six years, until March 2002. Between April 2002 to March 2005, only payable deposits received full deposit insurance protection. Time deposits were insured up to a 10 million yen cap. As of April 2005, all deposits (with the exception of payable deposits that are zero-interest earning, payable on demand and providing settlement services) in Japanese banks are insured only up to 10 million yen, reverting back to the pre-1995 situation. Fueda and Konishi (2007) find that Japanese depositors discipline the

¹⁷ Hoshi and Kashyap (1999) find that bank deregulation allowed large corporations to switch their funding sources from more costly bank loans to less expensive capital market financing. However, since deregulation did not offer new investment opportunities for consumer savings, households continued depositing their savings in banks. Thus, Japanese banks retained deposit sources of funds while losing much of their traditional large business-lending base. Japanese banks, in their search for new borrowers, therefore, increased their lending to small businesses and real estate lending. This increased real estate lending fueled the real estate bubble that built up in Japan during the 1980s. Uchida and Nakagawa (2007) and Hoshi, Kashyap and Scharfstein (1991) find evidence of irrational herding behavior among Japanese banks in the domestic loan market during the buildup of the credit bubble in Japan during 1987-1989.

¹⁸ For a complete list of deregulations packaged in Japan's financial liberalization programs, see Hoshi and Kashyap (2001).

¹⁹ Hoshi and Kashyap (2009), page 11.

banks when deposit insurance protection is incomplete by withdrawing their funds from risky banks and forcing these banks to restructure²⁰.

In March 1998, the Land Revaluation law was passed, allowing all Japanese banks (not just those with international branches as was the case for the equity securities revaluation allowance) to add 45% of their unrealized gains on land values to Tier 2 capital. In addition, risk-based capital requirements were extended to domestic Japanese banks without international branches, although the standard was 4%, not 8%. Because of the lower regulatory capital standard for domestic Japanese banks, general provisions and loan loss reserves could constitute only 0.625% of Tier 2 capital, as compared to the 1.25% level permitted for Japanese banks with international operations.²¹ Table 1 summarizes the capital requirements for Japanese banks with and without international branches during this time period.

INSERT TABLES 1 and 2 AROUND HERE

As the banking crisis in Japan continued, in February 1998, the Japanese government initiated a program of public infusions of capital, allocating 13 trillion yen for recapitalizing banks and 17 trillion yen for protecting the depositors of failed banks. Most of the injections of subordinated debt were directed toward the systemically important city and trust banks²². Moreover, the amount of capital was spread relatively evenly across the large banks. Despite this program, in 1998 two long-term credit banks, Long-term Credit Bank of Japan and Nippon Credit Bank failed and were nationalized. Thus, a second round of public capital infusions was undertaken during 1999, mostly in the form of preferred stock. As can be seen from Table 2, the 1999 program was far more substantial in size. Moreover, the level of each bank's capital injection was determined by the bank's non-performing loan levels.²³ During 1998 and 1999,

²⁰ Imai (2006) finds that the end of full insurance in March 2002 invoked depositors' discipline.

²¹ Prior to 1999, capital adequacy requirements for Japanese banks with international branches were calculated on a consolidated basis while that of domestic banks was calculated on an unconsolidated basis. This changed since March 1999 when capital adequacy requirements for all banks came to be reported both on an unconsolidated as well as a consolidated basis.

²² To save space, the details of the public injections, including the identities of the recipients and the details of the amount received by each recipient are outlined in Appendix A. Table 2 provides a comprehensive summary of the injections.

²³ Prior to 1993, Japanese banks were not required to report their non-performing loans in their financial statements. This requirement was gradually phased in until all banks began reporting non-performing loans from March 1998.

Japanese Government made public injections of about 10 trillion yen amounting to 2% of Japan's GDP in an attempt to boost Japanese bank capital adequacy ratios and stimulate bank lending activity. Given the slow recovery of the Japanese economy, public capital infusions continued through the 2000s (see Table 2). The Japanese government would periodically infuse capital to systemically important banks that faced a capital crunch due to non-performing loan losses.

In April 1999, mark-to-market requirements were extended to all securities held by Japanese banks. Moreover, tax deferred accounting became effective in Japan as of March 1999 permitting banks to increase their regulatory capital levels by including deferred tax assets (DTAs) in Tier 1 capital; see Skinner (2008). This was not a sign of financial health because the DTAs represented past loan losses that the banks would be able to deduct on their taxes if ever they became profitable.²⁴

In April 1998 (and revised in October 1998), Japanese banks were formally subjected to penalties from violations of capital regulations in the form of Prompt Corrective Action (PCA).²⁵ Prior to the adoption of PCA, capital requirements were used as managerial guidance for Japanese banks, but there were no formal penalties for noncompliance with capital standards. However, after the adoption of PCA, if a bank fell short of the minimum capital standard, it faced formal regulatory action. Bank capital ratios were divided into four classes, which mandated progressively stricter intervention as the capital ratio fell. For example, the first action class (requiring the deficient bank to submit and implement a management improvement plan with measures to enhance capital) was triggered if an international bank's capital fell between 4% to 8% or if a domestic bank's capital fell between 2% to 4%. If the international (domestic) bank's capital was between 2% to 4% (1% to 2%), dividend payouts and executive bonuses would be restricted. If the international (domestic) bank's capital was between 0% to 2% (0% to 1%), the bank was required to present plans to substantially increase capital enrichment or decrease business activity, or merge with another bank. Finally, if capital

²⁴ However, Skinner (2008) finds a statistically significant negative effect on Japanese bank capital adequacy in the first year of adoption of the provision allowing the use of deferred tax assets (DTAs). That is, the lower the bank's capital adequacy level, the higher the DTAs, thereby suggesting that DTAs were used to bolster the bank's capital position. In 2003, stricter audit procedures stated that if the bank's capital position fell below 4% then it was not allowed to use five years of DTAs as capital.

²⁵ Domestic banks got a one-year extension for the start of PCA that began from April 1999.

was entirely depleted, regulators would require the bank to discontinue operations. In December 2002, an early warning system was introduced in Japan so that bank regulators could monitor bank profitability and asset liquidity even if capital standards were met in order to detect unhealthy banks before they deteriorate into capital deficiency.

In October 2002, a program for financial revival was announced that required major banks to reduce their ratio of non-performing loans to total loans by half as of March, 2005. This program also codified the Bank of Japan's responsibilities to assist financial institutions in distress. In the event of a capital shortage or liquidity problem, the Bank of Japan would immediately offer the troubled bank "Special Support," which consisted of providing liquidity through special loans, public injections of funds, the placement of resident bank inspectors, and possible changes in the bank's management. Despite these policies, the Japanese banking system was weak and undercapitalized throughout the decade.

3. Data and Descriptive Statistics

3.1 Data Description

We hand collect a sample consisting of the financial statements of Japanese banks grouped into city, trust, long-term and regional banks. The regional banks are further grouped into two sub-groups: regional banks and regional banks of the second tier popularly referred to as "regional 2 banks."²⁶ Our original sample consisted of 17 city banks, 7 trust banks, 2 long-term banks, and 134 regional banks (69 regional banks, and 65 regional 2 banks). We only consider those banks that continue to exist throughout our sample period, which extends from the fiscal year for 1992 (beginning on April 1, 1992 and ending on March 31, 1993), through the fiscal year for 2006 (April 1, 2006 through March 31, 2007). If a bank merged during the sample period, following the methodology of Hancock and Wilcox (1992) and Bernanke and Lown (1991), we construct a hypothetical consolidated bank whose pre-merger value for any given variable is the sum of pre-merger values for the banks involved in the merger deal. For example, Mitsubishi

²⁶ In Japan, the second tier (regional 2) banks were originally established as mutual banks and were regulated separately from regional 1 banks. On February 1, 1989, 52 of 68 mutual banks were transformed to Banking Act regional banks and designated regional 2. By April 1, 1992, all remaining mutual banks completed their transformations to regional banks under the Banking Act.

Tokyo UFJ Bank was established as a result of a merger between Tokyo Mitsubishi Bank and the UFJ Bank on January 1, 2006. In our sample, the constructed Mitsubishi UFJ Bank represents the merged entity throughout our sample period. We then delete from our sample any banks that failed before 31st March 2007. Note that survivorship bias is not a concern here because our focus is on whether healthy Japanese banks responded to public stimulus policies. Correcting for mergers and failures, we obtain a clean sample comprising 4 city banks, 4 trust banks, 2 long-term credit banks and 107 regional banks (62 regional banks and 45 regional 2 banks).

Our data sources are twofold: one based on the Nikkei NEEDS Japanese database and another that is hand collected. We obtain financial variables (e.g., loans outstanding by industry or sector) from the unconsolidated bank financial data recorded in the Nikkei NEEDS database. In our analysis, we focus on three loan categories classified in the literature as bank-dependent loans: commercial and industrial loans, non-residential real estate loans, and residential real estate loans (see Peek and Rosengren (2001), Peek, Rosengren and Tootell (2003)).

Another major component of our analysis utilizes the variables measuring each bank's capital level. Japanese banks are required to report their Tier 1 and Tier 2 capital levels in their annual reports. Individual bank capital levels and their sub items including equity and land revaluation allowances are only available on NEEDS after 1999. Therefore, values of these variables before 1999 had to be hand collected from Japanese bank financial statements. Moreover, we hand collected data on each bank's loan losses for our sample period. To this end, we obtained approximately one thousand annual reports of individual banks for each bank-year observation archived in the Bank Library run by the Japanese Bankers' Association. To fill in missing values, we obtained the banks' securities reports archived at Keio University library. Both types of reports are archived only in a hard copy format requiring us to manually generate the current database that we utilize in this study. For data in the period after 1999, we checked the data reported in the financial reports against the Nikkei NEEDS database. In the case of any discrepancy, we consulted with bank managers. In all such instances, the data reported in the individual bank annual reports matched the estimates provided by the bank managers, and thus we adopted the data from the annual reports, thus ensuring

consistency of our data. From our cleaned sample, we had to drop Yasuda Trust bank due to lack of data on residential real estate loans. Therefore, our final sample reduced to 116 banks (4 city banks, 3 trust banks, 2 long-term credit banks and 107 regional banks) and 1,740 annual data points over the 1993 through 2007 period. The list of banks in our final sample is provided in Appendix B.

3.2 Model Description

We follow Peek and Rosengren (2005) and specify the model of bank lending activity as a function of macroeconomic conditions, bank characteristics, public policy interventions and capital regulations as follows:

$$\begin{aligned} ((L_{i,j,t} - L_{i,j,t-1})/A_{i,t-1}) = & a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t \\ & + a_4 \text{LOANLAG}_{i,j,t-1} + a_5 \text{CAPREQ}_{i,t-1} + u_{i,t} \end{aligned} \quad (1)$$

We summarize the list of dependent and explanatory variables in Table 3 and the summary statistics of the variables in Table 4.

INSERT TABLES 3 AND 4 AROUND HERE

The dependent variable is the change in outstanding loans of a bank i to sector j between the periods t and $t-1$ normalized by the total assets of bank i as of period $t-1$.²⁷ In our analysis, we consider four categories of dependent variables: aggregate loans (*TOTLOAN*), commercial and industrial loans (*CILOAN*), non-residential real estate loans (*NONRESLOAN*) and residential real estate loans (*RESLOAN*). On average, commercial and industrial loans, non-residential real estate loans and residential real estate loans jointly comprise 40% of total loans of the banks in our sample. Descriptive statistics of the sectoral allocation of loans is outlined in Table 4, Panel B. The largest loan segment for Japanese banks is residential real estate loans, although there is considerable commercial and industrial lending and non-residential real estate lending.

To capture a bank's lending behavior in the previous year, we include lagged values of the loans, denoted as (*TOTLOAN(-1)*, *CILOAN(-1)*, *NONRESLOAN(-1)*, *RESLOAN(-*

²⁷ Because of the absence of data on new lending flows, we utilize the net change in outstanding loans in our analysis. Note that the relationship between change in outstanding loans and new loans can be expressed as New Loans = Change in outstanding loans + Charge offs + Transfer of real estate loans to other real estate owned due to foreclosures + Loan sales (refer to Peek and Rosengren 2000 for details). Examination of the change in bank portfolio holdings is appropriate since our focus is on regulatory capital constraints.

l)), summarized in the vector **LOANLAG**. To conserve degrees of freedom, we used a single lag in our past loan values similar to Hoshi and Kashyap (2009).

One of the critical components of any analysis involving a bank's lending behavior is to control for the macroeconomic factors affecting loan demand to disentangle the impact of loan demand shocks from loan supply shocks. We specify the vector **DEMAND** that includes time varying macroeconomic variables that we collect from the Japan Statistical Yearbooks.²⁸ First, we use the annual growth rates of Japan's Gross Domestic Product (*GDP*); for city, trust and long term banks, we use national GDP, whereas for regional banks, we use prefecture level GDP where the prefecture is selected based on the location of the regional bank's headquarters. Further, we additionally control for macroeconomic variations using the *Index of Business Conditions (BUSINDEX)* collected from the Annual Survey of Corporate Behavior. *BUSINDEX* is a survey of Japanese businesses' forecasts of the future growth rate in consumer demand over the next year and next five years. Another variable used to control for macroeconomic factors is the *Consumer Confidence Index (CONSINDEX)* collected from the Monthly Consumer Confidence Survey in which urban consumers throughout Japan are asked to forecast their confidence about the economic conditions, particularly regarding their income growth and willingness to buy durable goods in future months and years. Both *BUSINDEX* and *CONSINDEX* are provided by the Economic and Social Research Institute of Japan. Finally, we include a set of annual dummy variables (*TIME DUMMIES*) summarized by the vector **YEAR** to control for the year-to-year variations in macroeconomic conditions and general economic environment.

CAPREQ is a vector summarizing each bank's capital position. While the reported Basel capital ratio provides a measure of a bank's capital position, to capture a bank's overall capital constraint, we include the difference between the reported Basel capital ratio and the target Basel capital ratio (*BISDIF*). A negative value indicates that a bank's reported capital ratio falls short of the target ratio mandated by the Basel Accord (8% for international banks) or the FSA (4% for domestic banks), and therefore the bank

²⁸ Peek and Rosengren (2000) address the endogeneity problem by utilizing the decline in Japanese commercial real estate prices as a natural experiment to test the extent to which a loan supply shock can affect real economic activity in the US.

is considered to be capital constrained. A value of zero or a positive value of the *BISDIF* variable indicates a bank meets or exceeds the target capital requirement.

In addition to the overall capital requirement, **CAPREQ** also includes variables consisting of Tier 2 regulatory capital forbearance policies, *LANDREVAL* and *EQREVAL*, which are measured as the allowances for land and equity securities revaluation divided by total assets.²⁹ In addition, we include two variables that measure public injections: *BLANKETPUBINJ* and *RISKBASEDPUBINJ*. The former is calculated as the amount of public injections in 1998 as a share of total assets. The latter includes the amount of public injections in year 1999 and thereafter as a share of total assets. In Japan, the two major phases of public injections were initiated in 1998 and in 1999. However, we find that the 1998 program was poorly conceived in comparison to the 1999 injection. In the blanket program initiated in 1998, all city banks applied for and received almost an equal amount of capital that was fixed at a maximum of 100 billion yen. This amount was set in consultation with the then healthiest bank, Bank of Tokyo Mitsubishi. Hence as Hoshi and Kashyap (2009) argue, the maximum amount disbursed (1.8 trillion yen) was far less than the amount needed to restore bank capital.

In comparison, the 1999 injection was much larger (7.5 trillion yen) and it was given after the Financial Reconstruction Commission (FRC) evaluated each bank's application to ascertain whether the amount requested would be enough to cover each bank's non-performing loan problem.³⁰ Since 1999, the government has periodically propped up troubled, systemically important banks³¹ with varying amounts of public injections although the aggregate amount is far less than the 1999 program (see Table 2).

INSERT FIGURE 1 AROUND HERE

Descriptive statistics for the explanatory variables in our analysis are presented in Table 4, Panel A. Figure 1 provides a pictorial depiction of the relative size of each

²⁹ We utilize total assets as the denominator to normalize each bank's capital position as a basis of comparison, because risk-adjusted assets are not available for domestic banks until 1997.

³⁰ Hoshi and Kashyap (2009) state that the increase in size of public injections in 1999 was the result of the Japanese government's rigorous assessment of the banks' non-performing loans, thereby allowing them to better assess each bank's needs.

³¹ The Act of Strengthening Financial Functions passed in 2004 allowed the Japanese government to inject funds into the banking system in 2007 (fiscal year 2006) without having to justify their systemic importance. However, since our sample ends in 2007 we do not utilize the 2007 public injections in our analysis. Thus, for our sample, all *RISKBASEDPUBINJ* in 1999 and thereafter are based on each bank's risk exposure and loan losses.

stimulus program. Public injections were, on average, lower than the indirect infusions provided by equity revaluations or land revaluations. The public injections of 1998 averaged 0.003% of assets across all banks in our sample. The public injections in 1999 and thereafter were substantially bigger in size, averaging 0.025% across all the banks. In contrast, equity (land) revaluations averaged 0.29% (0.18%) of bank assets. This is partly due to the fact that public injections were limited to the major banks (city, trust and long-term) with only a handful of regional banks receiving capital infusions. Thus, public injections covered a limited number of banks in our sample, although for those banks, the amount of capital infusions was quite substantial – with a maximum capital injection of 4.8% of the bank’s assets as compared to the maximum equity and land revaluation of 2.5% and 0.95% of assets, respectively. In terms of coverage, land revaluations were broadest in scope being applicable to all Japanese banks, whereas only banks with international operations could take equity revaluations³².

In our model, we utilize the following bank characteristic control variables. **BANK** is a vector of bank specific variables that summarize the health of a particular bank under consideration. We include log of assets (*ASSET*) as a measure of bank size, and dummy (0, 1) variables that specify the type of a bank: city bank (*CITY*), trust bank (*TRUST*) long-term credit bank (*LONG-TERM*), regional bank (*REGIONAL*). The binary variable for the fifth category, regional 2 banks, is omitted. Moreover, we include a binary variable (*DOMESTIC*) to capture a bank’s operational jurisdiction, such that *DOMESTIC* takes a value of 1 if a bank only has domestic operations and 0 if the bank has international operations in any given year. We also include a measure of loans made to failed enterprises as a share of the bank’s beginning of the period asset (*LOANLOSS*). The annual reports for the banks provide three possible measures of loan losses: loans to failed enterprises, loans whose interest payments have been suspended and loans whose interest payments have been suspended 3 months or more. While the data on the first category is available for the entire sample period, the data on the last two categories are only available since 1995 for all the banks in our sample. Given this restriction, we use loans to failed enterprises as a measure of loan losses incurred by a bank.

³² Another difference between direct public injections and the revaluation allowances is that the latter represented permanent, on-going infusions, whereas the public capital infusions were one-time episodes.

We estimate the model over the 1993-2007 period and present the results of our analysis in the next section.

4. Empirical Results

4.1. *The Efficacy of Japanese Public Policy Interventions*

INSERT TABLE 5 AROUND HERE

We test the impact of the three regulatory capital policy interventions (direct public injections of 1998, 1999 and the changes in accounting valuation procedures) using the variables *RISKBASEDPUBINJ*, *BLANKETPUBINJ*, *LANDREVAL* and *EQREVAL*. Table 5 presents the fixed effect regression results of the model specified in equation (1). Each column of Table 5 represents the estimation using each of the four dependent variables – total loans, commercial and industrial loans, non-residential mortgages and residential mortgages lending. The heteroskedasticity-robust standard errors are reported in the parentheses and are calculated using the Panel Corrected Standard Errors (PCSE) methodology suggested by Beck and Katz (1995). The results indicate that *RISKBASEDPUBINJ* had a significantly positive impact on aggregate bank lending across all loan types. The coefficients indicate that a 1% increase in the risk-based public injections received stimulate net outstanding loans (as a share of assets) by approximately 0.01% (coefficient significant at 1%). In contrast, the results from the across the board public injections *BLANKETPUBINJ* variable actually suggest that total bank lending declined.

In terms of sector-specific effects, risk-based public injections were most successful in stimulating commercial and industrial lending (coefficient positive and significant at 1%). The impact on loans made to non-residential real estate and the real estate sector is also positive though the coefficient is not significant at the 5% level.³³ In contrast, blanket public injections had no statistically significant impact on lending in any of the three sectors. Thus, the poorly designed public policy program of blanket injections applied to a small number of banks in 1998 was unsuccessful in accomplishing its goal of stimulating bank lending, although the program of risk-based capital infusions

³³ The coefficient on non-residential real estate loans is significant at 10%.

stimulated bank lending activity.³⁴ Thus, the results of our analysis presented in Table 5 show that risk-based direct infusions of capital had a stimulative effect on aggregate lending, as well as on each sector of lending³⁵.

In contrast, the size of both the equity and land revaluation allowances had no overall impact on aggregate lending – see column (1) of Table 5. However, the land revaluation allowance had an allocative effect, as shown in columns (3) and (4) of Table 5. Japanese banks increased their non-residential real estate lending and decreased their residential real estate lending (statistically significant at the 5% level or better) in response to the regulatory forbearance offered by Tier 2 capital infusions through land revaluation allowances. There is also a slight increase in commercial and industrial lending, although it is not statistically significant at the 10% level. Thus, Japanese banks did not expand their overall lending activity, but shifted from the residential mortgage sector to the non-residential real estate sector in response to regulatory capital arbitrage incentives³⁶.

Our regression results presented in Table 5 also indicate that the coefficient on *BISDIF*, each bank's excess over its capital requirement is statistically significant (at the 5% level or better) and positive for aggregate lending, and commercial and industrial loans, but was significantly negative (at the 5% level) for residential real estate loans. This demonstrates the reallocation of lending activity that is driven by bank capital constraints. Residential real estate lending is subject to lower capital requirements (50% risk weight) as compared to commercial and industrial lending (100% risk weight). Thus, Japanese banks that were more capital constrained (i.e., *BISDIF* is lower) reduced their business lending and shifted toward residential mortgage lending. In contrast, banks with excess capital (i.e., *BISDIF* is higher) reallocated their lending activity away from residential mortgages toward business lending. Moreover, the coefficient on *LOANLOSS*

³⁴ The effectiveness of the 1999 capital infusion policy is due to both the methodology (risk-based) and the size (over 7.4 trillion yen). When the post-1999 capital infusions are analyzed separately from the 1999 program, we find increases in aggregate and sectoral lending activity although the statistical significance is lower.

³⁵ Our results on aggregate lending are consistent with Giannetti and Simonov (2009) who find that the risk-based public injections had a statistically significant positive impact on aggregate lending whereas the effect of the blanket injection is not significant.

³⁶ This sectoral reallocation of loans is consistent with the *debt concentration effect* postulated by Gande et al. (2008). However, our micro evidence finds this effect in case of implicit bailouts engineered by the Land Revaluation Law rather than a direct bailout in the form of direct public injections.

was statistically significant (at the 1% level) and negative for all loan types except residential real estate (for which the coefficient is positive, albeit not significant), consistent with the inability of banks with high loan losses to increase their aggregate lending and lending to high risk-weighted sectors and instead focus their lending on the low risk-weighted residential real estate sector. The significant (at the 1% level) and positive coefficient on lagged total lending (e.g., the *TOTLOAN(-1)* variable) is consistent with Japanese banks' rolling over of past due loans into future loans in order to avoid loan write-downs (see Peek and Rosengren (2005) and Caballero, Hoshi and Kashyap (2008)).

4.2 *Controlling for Endogeneity*

The results, presented in Table 5 obtained by estimating our basic model, equation (1), suggest that Japanese bank lending activity was capital constrained. That is, Japanese bank capital levels impacted the banks' lending behavior either in terms of the aggregate lending activity or in terms of their allocation across lending sectors. However, this result may be impacted by endogeneity. As discussed in Section 2, Japanese bank capital regulations are bifurcated depending upon whether the bank has international operations or not. More lenient capital standards are required of domestic banks as compared to Japanese banks with international operations. This dichotomy was retained even as Japan adopted the Basel capital standard, since some elements of the capital requirements were applied to banks with international branches and not to banks with only domestic operations. Banks with only domestic operations must comply with only the 4%, rather than the 8% minimum capital requirement for international banks.

INSERT TABLE 6 AROUND HERE

Table 6 shows that on average domestic banks with lower capital requirements had larger excess capital positions than international banks. Thus, in order to reduce their regulatory capital requirements, many Japanese banks switched from an international charter to a domestic only charter by relinquishing their foreign activities. In Appendix C we outline the extent of switching by Japanese banks during the banking crisis. This switching was endogenous to Japanese banks' attempts to deal with the financial crisis by reducing their regulatory capital constraints. To examine bank reactions to the regulatory

intervention policies of the Japanese government, we model the endogenous decision to switch bank charter as a mechanism to relax regulatory capital constraints.

We hypothesize that banks with capital deficiencies were more likely to switch their charter. However, some of the public policy programs for international and domestic Japanese banks involved Tier 2 capital rather than Tier 1 capital. For example, the equity revaluation allowance represented an infusion of Tier 2 capital only into Japanese banks with international operations. Moreover, the land revaluation allowance represented a Tier 2 capital infusion for any Japanese bank that had positive land revaluations. However, this capital infusion would relax capital constraints only if the bank had no unused Tier 2 capital available – i.e., if the bank was Tier 2 capital-constrained. Under the Basel Accords, Tier 2 capital must be less than or equal to Tier 1 capital. Thus, a bank cannot use Tier 2 capital to meet more than the 4% minimum Basel requirement for Japanese banks with international operations or 2% for domestic Japanese banks.

We calculate the amount of unused Tier 2 capital (*UNUSEDTIER2*) by subtracting the amount of Tier 2 capital designated as meeting the bank's Basel capital requirement from the total amount of a bank's Tier 2 capital, i.e., all securities eligible for classification as Tier 2 capital minus Tier 2 capital actually used. The *UNUSEDTIER2* variable is normalized using the beginning of the period assets for each bank. The minimum value that this ratio can take is zero. A value of zero indicates that a bank has used all of its available capital that qualifies as Tier 2 in satisfying its capital requirements. A positive value for *UNUSEDTIER2* implies that the bank had excess Tier 2 capital that did not qualify for compliance with the Basel Capital Accord. The higher the value, the more constrained the bank is with regard to having sufficient Tier 1 capital to absorb all available Tier 2 capital. For example, if an international bank has Tier 2 capital of 5% of assets, but Tier 1 capital of only 3% of assets, then the bank's regulatory capital is deficient even though it has met the 8% total regulatory capital. Since Basel capital regulations require that Tier 1 capital be greater than or equal to Tier 2 capital, the bank's total capital position would be only 6% (3% of Tier 1 and 3% of Tier 2) and 2% of its Tier 2 capital would be unused. Such a bank may find it advantageous to switch its charter to a domestic only bank so as to reduce its capital requirement to 4% and

therefore be in compliance with regulatory capital standards. Thus, *UNUSEDTIER2* is an important variable determining whether the bank would have changed its charter to circumvent stricter capital requirements. Table 7 shows the breakdown of *UNUSEDTIER2* for international and domestic Japanese banks.

INSERT TABLE 7 AROUND HERE

Table 7 shows that unused Tier 2 capital cushion (to be able to absorb capital infusion due to revaluations) was low on average, and therefore a potentially binding constraint on exploiting the land and equity revaluation allowances. Moreover, this constraint was most binding for the international banks, which had a comparatively higher unused Tier 2 capital position as compared to the domestic banks. As expected, this disparity is most apparent till 1998, when the first wave of major switching happened³⁷. We therefore control for unused Tier 2 capital in our analysis.

In order to analyze the decision to switch bank charter to a domestic only bank, we utilize a probit model in a two-stage instrumental variables setting. The probit model is:

$$\Pr(\text{Switcher}_{i,t} = 1 | \bar{X}) = a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t + a_4 \text{LOANLAG}_{i,j,t-1} + a_5 \text{CAPREQ}_{i,t-1} + a_6 \text{INSTRUMENT}_{i,t-1} + u_{i,t} \quad (2)$$

where \bar{X} denotes the vector of explanatory variables on the right hand side of equation (2). The dependent variable has a value of 1 in the years during and after a bank's switching its charter, and 0 in the years before a bank switches its charter, or throughout the period if the bank does not change its charter at all during the sample period. The explanatory variables summarized in the vectors **BANK**, **DEMAND**, **YEAR**, **LOANLAG** and **CAPREQ** are summarized in Section 3.

In addition, we include the vector **INSTRUMENT** that summarizes the set of instrumental variables used. We utilize three instrumental variables: *UNUSEDTIER2*, *UNUSEDTIER2*EQREVAL*, and *UNUSEDTIER2*LANDREVAL*. These variables are chosen because the Tier 2 capital constraint is most relevant in determining whether the bank switched its charter to take advantage of the Japanese government's regulatory forbearance policies of the land and equity revaluations. These policies did not impact

³⁷ Thereafter, this constraint was partially released, in part, by international banks' switching of their charters to domestic banks.

Tier 1 capital, although the total capital constraint is incorporated into the model using the *BISDIF* variable. To further justify our choice of instruments, Table 8 presents the correlation matrix.

INSERT TABLE 8 AROUND HERE

UNUSEDTIER2 is positively correlated with the switching decision (significant at the 1% level), but is uncorrelated with all of the loan sector variables.

Thus, we utilize the *UNUSEDTIER2* along with *UNUSEDTIER2*EQREVAL* and *UNUSEDTIER2*LANDREVAL* (the two cross-product variables) as instruments.³⁸

INSERT TABLE 9 AROUND HERE

Table 9 presents the first stage results of the probit analysis. The dependant variable is a binary variable, *SWITCHER*, which takes on a value of one if the bank switches from an international to domestic only charter, zero otherwise. The results of the probit analysis of the bank charter switch decision are consistent with switching by large, relatively well-capitalized banks. That is, only if the bank's capital was within reach of meeting the capital requirements would the charter switch be effective, as indicated by the positive and significant (at the 1% level) coefficient on the *BISDIF* variable measuring the Basel capital ratio. Consistent with this decreased switching propensity for banks with greater deficiencies in bank capital requirements, banks with higher amounts of loan losses are less likely to switch (negative and significant (at the 1% level) coefficient on *LOANLOSS*). Switching was expected to benefit only those banks that were either marginally deficient or had excess regulatory capital.

Most importantly, the first stage probit results shown in Table 9 suggest that only those banks that potentially *could not* benefit from the land and equity revaluations (i.e., they have *UNUSEDTIER2* capital) were most likely to switch charters. First, the positive and significant (at the 1% level) coefficient on *UNUSEDTIER2* variable shows that the greater the Tier 2 capacity, the greater the probability of a switch in charter. In addition, the positive and significant (at 5% level or greater) coefficient on *LANDREVAL* and *UNUSEDTIER2*LANDREVAL* highlights the fact that banks with larger land revaluations had no qualms about switching charter as they were allowed to utilize land revaluation

³⁸ *BISDIF* measures the overall capital effect in terms of the bank's deviation from Basel capital requirements. However, because the *BISDIF* variable is positively correlated with the amount of commercial and industrial loans directly (see Table 8), we cannot use it as an instrumental variable.

excesses even under domestic charter. The propensity to switch charter for these banks was reinforced further if they had unused Tier 2 capital. In contrast, the negative and significant (at the 1% level) coefficient on the *UNUSED TIER 2 * EQREVAL* variable suggests that banks with large equity revaluation allowances are less likely to switch to a domestic charter since they could only use this regulatory capital forbearance if they have Tier 2 capacity available *and* if they have international operations. Thus, the probit analysis shows that bank capital regulations impacted Japanese banks' decisions to switch their operations from international to domestic only.

In order to measure the impact of public policy interventions during the Japanese banking crisis, while controlling for the endogenous decision to switch charters, we estimate a two-stage system that incorporates the endogenous charter switch model equation (2), into a second stage regression as follows:

$$\begin{aligned} ((L_{i,j,t} - L_{i,j,t-1}) / A_{i,t-1}) = & a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t \\ & + a_4 \text{LOANLAG}_{i,j,t-1} + a_5 \text{CAPREQ}_{i,t-1} + a_6 \text{SWITCHER}_{i,t-1} + u_{i,t} \end{aligned} \quad (3)$$

The dependent variable is regressed on the control variables as outlined in (1) and the variables outlined in the vector **SWITCHER**. Following Wooldridge (2006), the two-stage least square methodology regresses the dependent variable on the controls and the predicted value of the **SWITCHER**³⁹ as estimated in equation (2).

INSERT TABLE 10 AROUND HERE

The two-stage model results are presented in Table 10. Similar to the earlier fixed effect regression results (Table 5), the blanket public injections in 1998 have a negative effect on aggregate lending. In contrast, risk-based public injections had a strong positive impact on aggregate lending as well as across the sectors (the effect is even stronger in Table 10 when we control for switching as compared to our earlier result in Table 5). Moreover, the accounting rule changes (equity and land revaluations) have no impact on aggregate bank lending activity. Instead, only the land revaluation allowances have an allocative effect on bank lending, inducing a shift from residential to non-residential lending activity⁴⁰. These results are consistent with the OLS results presented in Table 5.

³⁹ We would like to thank William Greene for suggesting this step in our methodology.

⁴⁰ The result is even stronger as the coefficient for *LANDREVAL* for non-residential real estate loans is now positive and significant at 1% as compared to 5% in Table 5.

Endogenizing the switching decision demonstrates how Japanese banks exploited capital requirements. Both the OLS (Table 5) and two-stage (Table 10) results show that well-capitalized banks shifted from residential loans to commercial loans, and were able to increase their aggregate lending activity. In contrast, Japanese banks with large loan losses were forced to reduce their lending activity. Thus, our results are robust across model specifications, and suggest that Japanese bank capital levels, as indicators of bank solvency, impacted bank lending activity. Thus, public policies that stress bank solvency, as in the risk-based public injections that covered bank loan losses, were most efficacious in stimulating banking activity.

4.3 Robustness Test

As stated in Section 3, one of the major challenges of studying responses of banks to policy changes is to disaggregate the effect of policy changes from responses to changes in general macroeconomic conditions. While it is always difficult to adequately distinguish between the two, our vector **DEMAND** incorporated a list of variables that would control for shocks to lending behavior due to variations in the macroeconomy.

In addition to the variables included in DEMAND, a variable that has gained popularity in current literature (see Hoshi and Kashyap, 2009 and Campello, Graham and Harvey, 2009⁴¹) as a partial control for variations in macroeconomic conditions is lending attitudes of banks as perceived by their clients. For example, the Bank of Japan minutes (January 1998) state⁴²

“Members noted that the current phase of the economy featured (1) a substantial decline in private consumption, which had remained relatively stable in past economic recessions; (2) a significant deterioration of confidence in the economic outlook not only in the household sector but also the corporate and financial sectors, leading to amplified concern about the economy; and (3) a vicious circle created by interaction between the real economy and financial activity whereby an increasingly stagnant economy brought about a decline in stock prices, which led to more cautious financial institution behavior”

The TANKAN survey conducted quarterly by the bank of Japan provides us a measure on lending attitudes of banks as perceived by their clients (LENDATTITUDE) where the measure is calculated as a “diffusion index” that provides the percentage gap between the number of clients that experience an easy access to credit and those that find it harder to get credit. A shrinking or a negative value is indicative of a general

⁴¹ Campello, Graham and Harvey (2009) uses a measure of firms’ perception of their constraint to access funds to study the impact of financial crisis on a firm’s decision regarding employment, investment and capital spending.

⁴² This quote also appears in the working paper version of Hoshi and Kahyap (2009)

perception of tightening of credit access while an increasing or positive value is an indicator of a general perception of relative ease in accessing bank loans.

We extend our model, specifically the vector DEMAND to include LENDATTITUDE as an additional macroeconomic control and report the results of both our OLS and 2SLS analysis incorporating the new variable in Tables 11-13.

INSERT TABLE 11 AROUND HERE

The results of Table 11 are consistent with our previous OLS result (Tables 5) and once again establish the efficacy of risk-based public injections to stimulate aggregate lending while highlighting the failure of across the board public injections and changes in accounting valuation procedures to affect aggregate lending. Land revaluation allowances are effective, as witnessed earlier, in engineering an allocative shift in lending from residential real estate to non-residential real estate sector. As for our new variable, LENDATTITUDE, we find the coefficient to be positive and significant at 1% indicating that a perceived ease in lending attitudes by banks is associated with an expansion of aggregate lending. The effect seems to be strongest for the residential real estate loans.

INSERT TABLE 12 AND 13 AROUND HERE

We next conduct our 2SLS analysis including LENDATTITUDE as an explanatory variable. The results are consistent with the ones presented earlier (Tables 9 and 10). UNSEDTIER2 and its cross product with equity (UNSEDTIER2*EQREVAL) and land revaluation (UNSEDTIER2*LANDREVAL) once again emerges as an important determinant of the decision by the banks to switch charter from international to domestic, while LENDATTITUDE does not have any significant impact on the switching decision. As far as the efficacy of the regulatory intervention measures are concerned, our findings are consistent with our previous results that risk-based public injections are the most effective amongst the evaluated policies in easing aggregate bank lending, while changes in accounting valuation procedures, manifested in land revaluation allowance have an allocative effect. Broad based public injections and equity revaluations once again turn out to be ineffective in stimulating lending.

5. Conclusion

We utilize a unique, hand-gathered database of individual Japanese bank financial statements in order to assess whether three major regulatory capital interventions stimulated bank-lending activity during Japan's banking crisis. We find that public injections of capital into systemically important Japanese banks had a stimulative impact on bank lending, provided that the injections were based on each bank's loan losses and insolvency risk exposure.

Indirect intervention policies via accounting adjustments, such as land and equity revaluation allowances, did not have an impact on aggregate lending activity. However, the land revaluation allowance, which was substantial in size and applied to all Japanese banks, had an allocative effect on bank lending activity. That is, allowing the banks to declare past increases in land prices as a permanent component of Tier 2 capital enabled Japanese banks to shift their lending from residential mortgage lending to commercial lending and nonresidential real estate lending. Since these allowances were applied to all banks, they had a significant redistributive effect, whereas the restricted equity allowances (applied only to banks with international operations) did not. Our results are robust to incorporating an endogenous charter switching decision by the Japanese banks that relaxed the capital requirements.

We draw parallels with regulatory capital policies in the US, as well as provide a detailed survey of regulatory policies in Japan. Our results suggest that regulatory capital policies can be successfully used to stimulate overall economic activity if they are targeted to each individual bank's risk exposure. In a crisis, half measures are ineffective and can actually be detrimental. Public policy programs must be substantial in size and carefully applied.

Table 1: Summary of Japanese Bank Capital Requirements

	Until March 1997	From March 1998
International	<ul style="list-style-type: none"> · Banks are subject to the minimum standard of 8% with respect to the risk weighted Basel capital adequacy. · Unrealized gains on securities are included in Tier 2. · Net deferred tax assets are not included in regulatory capital. 	<ul style="list-style-type: none"> · Banks are subject to the minimum standard of 8% with respect to the risk weighted Basel capital adequacy. · Unrealized gains on securities are included in Tier 2. · Land revaluation is included in Tier 2. · Net deferred tax assets are included in Tier 1.
Domestic	<ul style="list-style-type: none"> · Banks are subject to the minimum standard of 4% with respect to the simple leverage ratio (not risk adjusted). · Unrealized gains on securities are not included in regulatory capital. · Net deferred tax assets are not included in regulatory capital. 	<ul style="list-style-type: none"> · Banks are subject to the minimum standard of 4% with respect to risk-weighted Basel I. · Unrealized gains on securities are not included in Tier 2. · Land revaluation is included in Tier 2. · Net deferred tax assets are included in Tier 1.

Table 2: Direct Public Capital infusions in Japan⁴³ (Data is in 100 million yen)

Year of Injection	Preferred stocks	Subordinated debts	Total
1998	3,210	14,946	18,156
1999	61,593	13,000	74,593
2000	5,550	200	5,750
2001	3,830	40	3,870
2002	1,840	0	1,840
2004	19,600	60	19,660
2007	405	0	405

⁴³ The details of public injections, including the identity of the recipients and the amount given to each recipient are outlined in Appendix A.

TABLE 3: Summary of the dependent and explanatory variables We provide a summary of the dependent and explanatory variables that are included in our regressions summarized in the three equations outlined below. Note that the explanatory variables have been grouped into vectors according to their role in affecting bank-lending behavior.

$$(1) ((L_{i,j,t} - L_{i,j,t-1})/A_{i,t-1}) = a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t + a_4 \text{LOANLAG}_{i,t-1} + a_4 \text{CAPREQ}_{i,t-1} + u_{i,t}$$

$$(2) \Pr(\text{Switcher}_{i,t} = 1 | \bar{X}) = a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t + a_4 \text{CAPREQ}_{i,t-1} + a_5 \text{INSTRUMENT}_{i,t-1} + u_{i,t}$$

$$(3) ((L_{i,j,t} - L_{i,j,t-1})/A_{i,t-1}) = a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t + a_4 \text{CAPREQ}_{i,t-1} + a_5 \text{SWITCHER}_{i,t-1} + u_{i,t}$$

This table extends to the next page.

DEPENDENT VARIABLES		
VARIABLE NAME	DESCRIPTION	
TOTLOAN	Net change in outstanding total loans as a share of beginning of the period assets.	
CILOAN	Net change in outstanding commercial and industrial loans as a share of beginning of the period assets.	
NONRESLOAN	Net change in non-residential real estate loans as a share of beginning of the period assets.	
RESLOAN	Net change in residential real estate loans as a share of beginning of the period assets.	
EXPLANATORY VARIABLES		
VECTOR	VARIABLES INCLUDED IN THE VECTOR	DESCRIPTION
BANK	ASSET	Log of beginning of the period assets
	CITY	A binary variable that takes the value “1” for city banks, and “0” otherwise
	TRUST	A binary variable that takes the value “1” for trust banks, and “0” otherwise
	LONG-TERM	A binary variable that takes the value “1” for long-term credit banks, and “0” otherwise
	REGIONAL	A binary variable that takes the value “1” for regional banks, and “0” otherwise
	DOMESTIC	A binary variable that takes the value “1” for banks with a domestic charter, “0” otherwise
	LOANLOSS	Loans to failed enterprises as a share of beginning of the period assets
DEMAND	GDP	Percentage changes in the annual Gross Domestic Product. For city, trust and long-term banks, we look at national GDP, for regional banks we look at the prefecture level GDP where the bank is headquartered.
	BUSINDEX	Index of Business Conditions,
	LENDATTITUDE	Diffusion Index of lending attitudes of banks as perceived by their clients.
	CONSINDEX	Consumer Confidence Index
YEAR	ANNUAL TIME DUMMIES	Binary variables for each of the years in the sample
LOANLAG	TOTLOAN(-1)	Change in total outstanding loans as a share of beginning of the period assets, lagged one period.
	CILOAN(-1)	Change in outstanding commercial and industrial loans as a share of beginning of the period assets, lagged one period.

	NONRESLOAN(-1)	Change in outstanding non-residential real estate loans as a share of beginning of the period assets, lagged one period
	RESLOAN(-1)	Change in outstanding residential real estate loans as a share of beginning of the period assets, lagged one period.
CAPREQ	BISDIF	Difference between the reported Basel capital ratio and the target Basel capital ratio
	BLANKETPUBINJ	Public injections in 1998 as a share of beginning of the period assets
	RISKBASEDPUBINJ	Public injections in 1999 and thereafter as a share of beginning of the period assets
	EQREVAL	Unrealized gains on equity as a share of beginning of the period assets
	LANDREVAL	Unrealized gains on land holdings as a share of beginning of the period assets
SWITCHER	SWITCHER	Binary variable that takes a value “1” in the years during and after a bank’s switching its charter, and “0” in the years before a bank switches its charter, or throughout the period if the bank does not change its charter at all during the sample period
INSTRUMENTS	UNUSEDTIER2	Unused tier 2 capital calculated as the difference between the capital that qualifies as tier 2 and the amount of capital actually included as tier 2 in calculating the capital adequacy ratio. The variable is expressed as a share of beginning of the period assets.
	UNUSEDTIER2*EQREVAL	Cross product of UNUSEDTIER2 and EQUITY REVALUATION
	UNUSEDTIER2*LANDREVAL	Cross product of UNUSEDTIER2 and LAND REVALUATION

Table 4: Descriptive Statistics - The sample of comprises of 4 city banks, 3 trust banks and 2 long-term banks, 62 regional banks and 45 regional banks that belong to the second tier. Mean, Median, Standard deviation, Maximum and Minimum are calculated over the sample period 1993 to 2007. The data on public injections begin in 1998 when the first round of public injections took place. The public injections were targeted at the major banks (city, trust and long-term) and only a few regional banks were the beneficiaries. The data on land revaluation is available from 1999 when most banks that availed of the Law Concerning the Revaluation of Land updated their balance sheets to reflect land revaluation. From a balance sheet perspective, public injections and land revaluations are taken as zero for the preceding years. Equity revaluations, on the other hand, have been allowed in Japan to be calculated as a part of bank capital since the adoption of the Basel Accord in 1988. However, while both international and domestic banks are allowed to count land revaluations as a part of tier II capital, only international banks have the option of including equity revaluation in their calculation of tier II capital. Hence for the domestic banks and the banks that switched charter to domestic any time during our sample period, equity revaluation is counted as zero.

	Mean	Median	Standard Deviation	Max	Min	Number of Observations
PANEL A: The descriptive statistics of explanatory variables used in our regressions						
ASSET (in log)	14.57	14.53	1.21	19.06	12.3	1740

UNUSEDTIER2*EQREVAL	0.046%	0.00%	0.69%	1.58%	0.00%	1738
UNUSEDTIER2*LANDREVAL	0.014%	0.00%	2.46%	0.00%	0.08%	1738
PANEL B: Distribution of Loans (as a percentage of total loans)						
CILOAN	13.38%	13.06%	5.35%	31.66%	1.28%	1740
NONRESLOAN	10.08%	9.09%	5.05%	56.79%	2.03%	1740
RESLOAN	16.2%	15.22%	8.48%	69.97%	3.06%	1718

Figure 1: Direct Public Injections, Equity Revaluation and Land Revaluation as a percentage of assets during the sample period 1993-2007-We plot the amount of total public injections, equity revaluations and land revaluations as a percentage of assets for each Japanese bank in our sample.

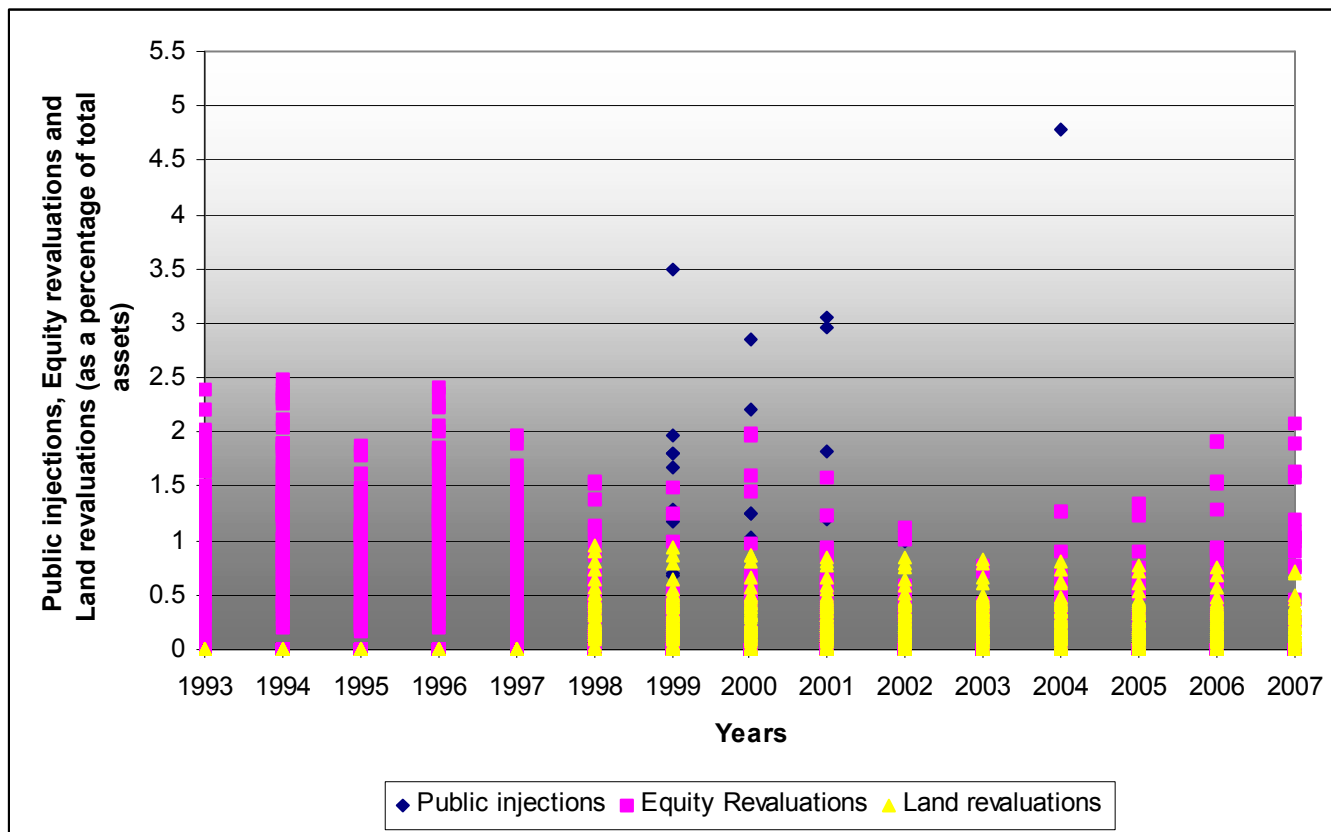

Table 5: Fixed Effect Estimation of the effect of regulatory capital remedies on changes in outstanding loans- The dependent variables in our regressions are the changes in outstanding loans, aggregate and by sectors, as a share of beginning of the period asset. We use fixed effect regression techniques and run the following regression: $((L_{i,j,t} - L_{i,j,t-1})/A_{i,t-1}) = a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t + a_4 \text{LOANLAG}_{i,t-1} + a_5 \text{CAPREQ}_{i,t-1} + u_{i,t}$
The details of the variables are summarized in Table 3. Our estimation also controls for bank-type dummies, annual dummies and the bank operations dummy that controls for the area of bank operations-international or domestic, though the coefficients are not shown in the table. The heteroskedasticity-consistent standard errors are in parentheses. *, **, *** indicate significance at 10%, 5% and 1% levels respectively.

⁴⁴ Minato bank switched in 1993 so for purposes of our sample, is considered a domestic bank for the entire sample period.

⁴⁵ Ashikaga bank also changed status to domestic in 1998 but it is not included in our sample as it failed during our sample period.

⁴⁶ Yasuda trust changed status in 2000 but is not included in our sample as residential real estate loan data is missing.

Table 7: Unused Tier II capital as a share of asset- According to the Basel capital regulations, Tier 2 capital cannot exceed 50% of Tier 1 capital. The *UNUSEDTIER2* variable is defined as the amount of Tier 2 capital designated as meeting the bank's Basel capital requirement minus the total amount of a bank's Tier 2 capital, i.e., all securities eligible for classification as Tier 2 capital minus Tier 2 capital actually used. The *UNUSEDTIER2* variable is normalized using the beginning of the period assets for each bank. The minimum value that this ratio can take is zero. A value of zero indicates that a bank has used all of its available capital that qualifies as Tier 2 in satisfying its capital requirements. A positive value for *UNUSEDTIER2* implies that the bank had excess Tier 2 capital that did not qualify for compliance with the Basel Capital Accord. The higher the value, the more constrained the bank is with regard to having sufficient Tier 1 capital to absorb all available Tier 2 capital.

Unused tier 2 capital as a share of assets – international and domestic banks

⁴⁷ Minato bank switched in 1993 so for purposes of our sample, is considered a domestic bank for the entire sample period.

⁴⁸ Ashikaga bank also changed status to domestic in 1998 but it is not included in our sample as it failed during our sample period.

⁴⁹ Yasuda trust changed status in 2000 but is not included in our sample as residential real estate loan data is missing.

Table 8: Correlation Matrix-We trace the correlations amongst the variables. ***, **, * indicate significance at 1%, 5% and 10% levels respectively.

Note that to conserve space we are not plotting the correlations with respect to our indices- CONSINDEX, BUSINDEX and LENDATTITUDE. Readers interested in the complete correlation matrix (inclusive of the indices) can get it from the corresponding author.

Table 9: 1st stage probit estimation of the probability of switching- The dependent variable takes a value 1 for the bank-year observations when a bank changes its charter from international to domestic and is 0 otherwise. We run the following regression:

$$\Pr(\text{Switcher}_{i,t} = 1 | \bar{X}) = a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t + a_4 \text{LOANLAG}_{i,t-1} + a_5 \text{CAPREQ}_{i,t-1} + a_6 \text{INSTRUMENT}_{i,t-1} + u_{i,t}$$

The details of the variables are summarized in Table 3. Our estimation also controls for bank-type dummies, annual dummies and the bank operations dummy that controls for the area of bank operations-international or domestic, though the coefficients are not shown in the table. The heteroskedasticity-consistent standard errors are in parentheses. *, **, *** indicate significance at 10%, 5% and 1% levels respectively.

Table 10: 2SLS Regression of the effect of regulatory capital remedies on changes in outstanding loans with endogenous charter switching decision- We endogenize the decision by many Japanese banks to switch charter from international to domestic and evaluate the impact of regulatory policy changes after controlling for the decision to switch. The dependent variable is the change in outstanding loans- aggregate and sector-wise- as a share of beginning of the period assets. We run the following regression:

$$\begin{aligned} ((L_{i,j,t} - L_{i,j,t-1}) / A_{i,t-1}) = & a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t + a_4 \text{LOANLAG}_{i,t-1} \\ & + a_5 \text{CAPREQ}_{i,t-1} + a_6 \text{SWITCHER}_{i,t-1} + u_{i,t} \end{aligned}$$

The details of the variables are summarized in Table 3. Our instrument is the predicted value of switching that we estimate from our first stage probit regression and the predicted value of switching interacted with LANDREVAL following Wooldridge (2006). Our estimation also controls for bank-type dummies, annual dummies and the bank operations dummy that controls for the area of bank operations-international or domestic, though the coefficients are not shown in the table. The heteroskedasticity-consistent standard errors are in parentheses. *, **, *** indicate significance at 10%, 5% and 1% levels respectively.

Table 11: Robustness Check: Fixed Effect Estimation of the effect of regulatory capital remedies on changes in outstanding loans- The dependent variables in our regressions are the changes in outstanding loans, aggregate and by sectors, as a share of beginning of the period asset. We use fixed effect regression techniques and run the following regression: $((L_{i,j,t} - L_{i,j,t-1})/A_{i,t-1}) = a_0 + a_1 \text{BANK}_{i,t-1} + a_2 \text{DEMAND}_{t-1} + a_3 \text{YEAR}_t + a_4 \text{LOANLAG}_{i,t-1} + a_5 \text{CAPREQ}_{i,t-1} + u_{i,t}$

The variables are the same as in Table 5 except that we append the model to include LENDATTITUDE-a series from TANKAN survey that measures how relaxed or tight firms perceive the lending attitudes of banks to be. Our estimation also controls for bank-type dummies, annual dummies and the bank operations dummy that controls for the area of bank operations-international or domestic, though the coefficients are not shown in the table. The heteroskedasticity-consistent standard errors are in parentheses. *, **, *** indicate significance at 10%, 5% and 1% levels

Appendix B: Data Appendix: In this appendix, we provide the comprehensive list of banks included in our sample. In the footnote, we describe the details of the mergers that took place during our sample period. We also list the banks that failed anytime during our sample period. This table extends to the next two pages.

PANEL A: COMPREHENSIVE LIST OF BANKS INCLUDED IN OUR SAMPLE					
CITY BANKS	TRUST BANKS	LONG-TERM CREDIT BANKS	REGIONAL BANKS	REGIONAL2 BANKS	
Mizuho ⁵⁰	Mitsubishi Trust ⁵¹	UFJ Nippon Credit	Hokkaido		Hokuyo
Tokyo Mitsubishi Resona ⁵³	Sumitomo Trust	Shinsei (Long Term Credit)	Aomori		Sapporo
	Chuo Trust ⁵⁴	Mitsui Yasuda Trust ⁵⁶	Michinoku		Yamagata Shiawase
Sumitomo Mitsui ⁵⁵			Akita		Kirayaka
			Shonai		Kitanippon
			Yamagata		Sendai
			Iwate		Fukushima
			Tohoku		Daito
			77		Towa
			Toho		Tochigi
			Gunma		Ibaragi
			Joyo		Keiyo
			Kanto Tsukuba ⁵⁷		Higashinippon
			Musashino		Tokyo Sowa
			Chiba Kogyo		Kanagawa
			Chiba		Daiko
			Tokyo Tomin		Nagano
			Yokohama		Toyama Daiichi
			Daishi		Fukuho
			Hokuetsu		Shizuoka Chuo
			Yamanashi Chuo		Gifu
			Hachijuni		Aichi
			Hokuriku		Nagoya
			Toyama		Chukyo
			Hokkoku		Daisan
			Fukui		Biwako

⁵⁰ Mizuho was formed by a merger of Daiichi Kangyo (city bank) with Fuji (city bank) and Industrial Bank of Japan (Long-term credit bank) in 2003.

⁵¹ Mitsubishi UFJ Trust was formed by a merger of Mitsubishi Trust (trust bank), UFJ Trust (trust bank) and Nippon Trust (trust bank). Mitsubishi Trust acquired Nippon Trust in 2002 and Mitsubishi Trust and UFJ Trust merged in 2006.

⁵² Mitsubishi Tokyo UFJ was formed by a merger of Mitsubishi (city bank) with Tokyo (city bank) and UFJ (city bank). Mitsubishi merged with Tokyo in 1997 and then merged with UFJ in 2006.

⁵³ Resona Financial Group was formed by a merger of Asahi (city bank) with Daiwa (city bank) in 2003. Resona FG has Resona (city bank) and Saitama Resona (city bank) as its subsidiaries. Resona and Saitama Resona continue to form the hypothetical Resona after the merger.

⁵⁴ Chuo Mitsui Trust was formed by a merger of Mitsui Trust (trust bank) and Chuo Trust (trust bank) in 2001.

⁵⁵ Mitsui Sumitomo was formed by a merger of Sakura (city bank) with Sumitomo (city bank) and Wakashio (regional 2 bank). Sakura merged with Sumitomo in 2002. Wakashio was acquired in 1999.

⁵⁶ Yasuda Trust was ultimately dropped from our sample due to lack of residential real estate loan data.

⁵⁷ Kanto Tsukuba was formed by a merger of Kanto (regional bank) and Tsukuba (regional 2 bank) in 2004.

	Hokkaido	March 1996			Ogaki Kyoritsu	March 2002	
	Aomori	March 1998			Juroku	March 2004	
	Akita	March 1998			Mie	March 1998	
	Yamagata	March 1998			Hyakugo	March 1999	
	Iwate	March 1998			Kyoto	March 1999	
	77	March 1999			Osaka	March 1996	
	Toho	March 1998			Senshu	March 1997	
	Ashikaga ⁷³	March 1998			Ikeda	March 1997	
	Joyo	March 2003		Regional 2 Banks	Nanto	March 1998	
	Musashino	March 1998			Kiyo	March 1998	
	Chiba Kogyo	March 1998			Sanin Godo	March 2002	
	Tokyo Tomin	March 2000			Hokuyo	March 1998	
	Yokohama	March 1999			KitaNippon	March 1998	
	Daishi	March 2000			Keiyo	March 1998	
					Aichi	March 1998	
					Nagoya	March 1999	

⁷² Yasuda Trust is the only bank that switched back from domestic to international charter during our sample period (March 2003). However, we exclude Yasuda Trust from our final sample as data for residential real estate loans, one of our primary dependant variables, is missing for the entire sample period.

⁷³ Ashikaga Bank is dropped from our final sample since data is missing after 2003.

Hokuetsu	March 1998	Chukyo	March 1998
