A State Space Approach to Estimating the Integrated Variance and Microstructure Noise Component *

Daisuke Nagakura † and Toshiaki Watanabe †

SUMMARY

We call the realized variance (RV) calculated with observed prices contaminated by microstructure noises (MN) the noise-contaminated RV (NCRV) and refer to the component in the NCRV associated with the MNs as the MN component. This paper develops a state space method for estimating the integrated variance (IV) and MN component simultaneously. We represent the NCRV by a state space form and show that the state space form parameters are not identifiable; however, they can be expressed as functions of fewer identifiable parameters. We illustrate how to estimate these parameters. The proposed method is applied to yen/dollar exchange rate data.

Key Words: Realized Variance; Integrated Variance; Microstructure Noise; State Space; Identification; Exchange Rate

1 Introduction

The variance of financial asset returns is known to change over time. More specifically, the variance, or the square root of the variance (volatility), tends to be large (small) following successive large (small) variances in previous periods. This phenomenon is known as "volatility clustering". A large number of researchers have tried to estimate these changing variances because their values are crucially important for option pricing, risk management, optimal portfolio construction, etc. There are two popular classes of models for this sort of volatility dynamics, namely, generalized autoregressive conditional heteroskedastic (GARCH) models and stochastic volatility (SV) models. Based on GARCH or SV models with estimated model parameters, one can estimate the changing variances. See, for example, Bollerslev et al. (1994), Palm (1996) and Zivot (2008) for comprehensive surveys on GARCH models, Glysels et al. (1996) for a review of some of the older papers on SV models and Shephard (2005) for a list of selected papers in the SV model literature.

Our main objective in this paper is to estimate the changing variances, or integrated variance (IV). The IV is a measure of the variability of financial asset returns over a specified period, for example, a day (a formal definition of IV will be given in Section 2). Recently, a new class of estimators for the IV has been developed by Barndorff-Nielsen and Shephard (2001), Barndorff-Nielsen and Shephard (2002), Andersen, Bollerslev, Diebold and Ebens (2001) and Andersen, Bollerslev, Diebold and Labys (2001). The estimator is called the realized variance (RV). The RV employs high frequency financial time series data such as minute-by-minute return data or entire records of quote or transaction price data. The RV is a model-free estimator in the sense that we do not have to specify the volatility dynamics. Under moderate assumptions, the RV converges in probability to the IV, as the sampling frequency tends to be high.

One of the key assumptions needed for the consistency of the RV is that there are no measurement errors in observed log-prices. The measurement error is called microstructure noise (MN) and emerges because of, for example, discreteness of prices, bid-ask bounce and infrequent trading, etc. When this assumption is violated, the RV is no longer a consistent estimator for the IV. It can be shown that, under the existence of MN, the RV diverges as the sampling frequency increases. Several alternative estimators of the RV, which are consistent even under the existence of MN, have been proposed by Zhou (1996), Zhang et al. (2005), Hansen and Lunde (2006), Bandi and Russell (2006) and Barndorff-Nielsen et al. (2008). See also Bandi and Russell (2008), who consider a mean-squared-error optimal sampling theory for reducing the effect of MN.

We call the RV calculated with observed log-prices contaminated by MN the noise-contaminated RV (NCRV) and refer to the component in the NCRV associated with the MN as the MN component (a formal definition of the NCRV and MN component is given in Section 2.3). We propose a state space approach to estimating the IV and MN components simultaneously. Our approach is an extension of the state space method proposed by Barndorff-Nielsen and Shephard (2002), who consider a situation with no MN. In this situation, Barndorff-Nielsen and Shephard (2002) show that the IV follows an ARMA process for some specific continuous-time SV models. Barndorff-Nielsen and Shephard (2002) also show that the RV can be represented as a state space form, namely, the sum of the IV and a discretization error, which is a white noise uncorrelated with the IV. Thus, given the state space form parameters, one can apply the Kalman filter to filter out the discretization error. Simulation study by Barndorff-Nielsen and Shephard (2002) demonstrates that the estimates of IV series by Kalman smoother have much smaller mean squared error than the RV series itself. This ARMA representation result is further developed by Meddahi (2003). Meddahi (2003) shows that the IV follows an ARMA process for a general class of continuous-time SV models, which is called the square root stochastic autoregressive variance (SR-SARV) model (Andersen, 1994; Meddahi and Renault, 2004). Meddahi (2003) derives explicit relationships between the ARMA model parameters and the SV model parameters.

We develop the state space method by Barndorff-Nielsen and Shephard (2002) for dealing with the problem of MN. We assume that an observed log-price is the sum of the true log-price and an i.i.d. MN. We represent the NCRV by a state space form in that the NCRV is the sum of three

\footnote{We interchangeably use the term "ARMA process" and "ARMA model" in this paper.}
unobserved components: the IV, which follows an ARMA process, a white noise (discretization error) and a MN component, which follows a MA(1) process. By applying the results of Granger and Morris (1976), we show that the sum of these three components, namely, the NCRV, follows an ARMA process. This ARMA process can be regarded as the (unique) reduced form of the state space form. The existence of MN component introduces many complexities in the identification of the state space form parameters. It is shown that the number of state space form parameters of the NCRV is more than the autocovariance structure of the NCRV can uniquely determine. In other words, the state space form parameters of the NCRV are not effectively identified in the sense that different sets of parameter values can give the same autocovariance structure. See Section 4 for more details.

We show that the state space form parameters can be expressed as functions of the unconditional mean and variance parameters of the underlying continuous-time SV model and parameters regarding MN (the variances of the MN and its square). Then, we prove that these parameters are uniquely identified. We illustrate how to estimate these identifiable parameters and the state space form parameters. With estimates of the state space form parameters, one can estimate the IV and MN components simultaneously by applying the Kalman filter to the state space form. One advantage of our method, compared with other existing methods, is that it can filter out not only the MN components but also the discretization errors. The proposed method is applied to yen/dollar spot exchange rate data. We find that the magnitude of the (daily) MN component is, on average, about 21% - 48% of the (daily) NCRV, depending on the sampling frequency.

The rest of the paper is organized as follows. In the next section, we introduce the class of SV models employed in this paper and define formally the IV, IV, MN and MN component. In Section 3, we briefly summarize the results in Meddahi (2003) on the ARMA representation of the IV. In Section 4, we explain our state space approach in detail. In Section 5, we conduct an empirical analysis applying our method to the yen/dollar spot exchange rate. The last section provides a summary and concluding remarks. Appendix A provides details on the derivations of the equations in the text. Some results are presented in Appendix B.

2 SR-SARV model, IV, RV and MN

2.1 Square root stochastic autoregressive variance (SR-SARV) model

Let \( p(t) \) be the log of the (efficient) spot price at time \( t \). Throughout the paper, we assume that \( p(t) \) follows the SR–SARV model considered in Meddahi (2003), which is given by the following class of continuous-time SV models:

\[
dp(t) = \sigma(t) \, dw_t, \quad \sigma^2(t) = \sigma^2 + \omega_1 P_1(f(t)) + \omega_2 P_2(f(t)),
\]

where \( f(t) \) is a state-variable process and the functions \( P_1(\cdot) \) and \( P_2(\cdot) \) are defined so that:

\[
E[P_1(f(t))], E[P_2(f(t))] = 0, \quad \text{var}[P_1(f(t))] = \text{var}[P_2(f(t))] = 1, \\
\text{cov}[P_1(f(t)), P_2(f(t))] = 0, \\
E[P_1(f(t + h))|f(s), p(s), s \leq t] = \exp(-\lambda_1 h) P_1(f(t)), \\
E[P_2(f(t + h))|f(s), p(s), s \leq t] = \exp(-\lambda_2 h) P_2(f(t)), \quad \forall h > 0,
\]

where \( \lambda_1 \) and \( \lambda_2 \) are positive real numbers. The unconditional mean and variance of \( \sigma^2(t) \) are \( E[\sigma^2(s)] = \sigma^2 \) and \( \text{var}[\sigma^2(s)] = \omega_1^2 + \omega_2^2 \), respectively. Let \( \kappa_1 = \exp(-\lambda_1) \) and \( \kappa_2 = \exp(-\lambda_2) \). Hereafter, we work mainly with \( \kappa_1 \) and \( \kappa_2 \) instead of \( \lambda_1 \) and \( \lambda_2 \) because it is more convenient for describing our results. Thus, the model has a total of five free parameters: \( \sigma^2, \omega_1^2, \omega_2^2, \kappa_1 \) and \( \kappa_2 \).

The model given in (1) and (2) is called the “two-factor SR–SARV model”. When \( \omega_2 = 0 \), the model is referred to as the “one-factor SR–SARV model”. The SR-SARV model includes many known models, such as constant elasticity of volatility processes, GARCH diffusion models (Nelson, 1990), eigenfunction stochastic volatility models (Meddahi, 2001) and positive Ornstein–Uhlenbeck Levy-driven models (Barndorff-Nielsen and Shephard, 2001). See Meddahi (2003) for more details.
2.2 Integrated and realized variances

Given the process of $\sigma^2(t)$, the IV is defined as

$$ IV_t \equiv \int_{t-1}^{t} \sigma^2(s) ds, \quad t = 1, 2, \ldots, $$

where the unit of $t$ is determined depending on the research objective. For example, if the researcher is interested in changes in variances of daily (weekly) returns, $t$ is interpreted as a day (week).

Under moderate assumptions, we can consistently estimate the IV by the estimator known as the RV, which is defined as

$$ R_{V_t}^{(m)} = \sum_{i=1}^{m} \frac{r_{i-1}^{(m)^2}}{n}, $$

where $r_{i}^{(m)} \equiv p(t) - p(t - \frac{1}{m}) = \int_{t-\frac{1}{m}}^{t} \sigma(s) dW(s)$, and $m$ is a positive integer. Here, and hereafter, the notation "(m)" implies that its value depends on the sampling frequency $m$. For example, if $t$ denotes a day and we take observations every five minutes, then $m = 288$. In this case, $r_{i}^{(288)}$ denotes a five-minute return, because one day is 5 x 288 minutes. It is well known that, as $m \to \infty$, $R_{V_t}^{(m)} \to IV_t$ (see, e.g., Barndorff-Nielsen and Shephard, 2002).

For the two-factor SR–SARV model, the variance and autocovariances of $IV_t$ are expressed in terms of the SV model parameters as:

$$ \text{var}[IV_t] = \frac{2\omega_1^2 (\kappa_1 - \log \kappa_1 - 1)}{(\log \kappa_1)^2} + \frac{2\omega_2^2 (\kappa_2 - \log \kappa_2 - 1)}{(\log \kappa_2)^2}, $$

$$ \text{cov}[IV_t, IV_{t-1}] = \frac{\omega_1^2 (1 - \kappa_1)^2}{(\log \kappa_1)^2} + \frac{\omega_2^2 (1 - \kappa_2)^2}{(\log \kappa_2)^2}, \quad \text{and} $$

$$ \text{cov}[IV_t, IV_{t-2}] = \frac{\omega_1^2 \kappa_1 (1 - \kappa_1)^2}{(\log \kappa_1)^2} + \frac{\omega_2^2 \kappa_2 (1 - \kappa_2)^2}{(\log \kappa_2)^2}. $$

Let $d_{t}^{(m)} \equiv R_{V_t}^{(m)} - IV_t$ and $\sigma_d^{2(m)} \equiv \text{var}[d_{t}^{(m)}]$. For $m \geq 1$, we have:

$$ \sigma_d^{2(m)} = \frac{2\sigma^4}{m} + \frac{4\omega_1^2 m}{(\log \kappa_1)^2} (\kappa_1^{1/\theta} - \log \kappa_1^{1/\theta} - 1) + \frac{4\omega_2^2 m}{(\log \kappa_2)^2} (\kappa_2^{1/\theta} - \log \kappa_2^{1/\theta} - 1). $$

It can be shown that $\sigma_d^{2(m)} \to 0$ as $m \to \infty$. See Meddahi (2003) for the above results.

2.3 MN component

Now assume that the observed log-price $p^*(t)$ is contaminated by a measurement error or MN so that:

$$ p^*(t) = p(t) + \varepsilon(t). $$

We assume the following properties of MN $\varepsilon(t)$.

Assumption 1

(a) $\varepsilon(t) \sim i.i.d.(\theta, \sigma^2)$ with $\sigma^2 \equiv \text{var}[\varepsilon^2(t)] < \infty$.

(b) $\varepsilon(t)$ is independent of $p(s)$ for all $s$ and $t$. 

We do not assume any specific distribution for $\varepsilon(t)$.

The observed return $r_i^{*}(m)$ is defined as:
\[
r_i^{*}(m) = p^*(t) - p^*(t - \frac{1}{m}) = r_i^{(m)} + e_i^{(m)},\]
where $e_i^{(m)} \equiv \varepsilon(t) - \varepsilon(t - \frac{1}{m})$. It is easy to show that
\[
E[e_i^{(m)}] = 0, \quad \text{var}[e_i^{(m)}] = 2\sigma_\varepsilon^2 \quad \text{and} \quad \text{cov}[e_i^{(m)}, e_{i+1}^{(m)}] = \begin{cases} -\sigma_\varepsilon^2, & i = 1, \\ 0, & i \geq 2. \end{cases}
\]

Note that $\text{var}[e_i^{(m)}]$ and $\text{cov}[e_i^{(m)}, e_{i+1}^{(m)}]$ do not depend on $m$. We define the NCRV, denoted by $RV_i^{*}(m)$, as
\[
RV_i^{*}(m) = \sum_{t=1}^{m} r_t^{*}(m) = RV_i^{(m)} + u_i^{(m)},
\]
where
\[
u_i^{(m)} \equiv 2 \sum_{t=1}^{m} r_{t-1}^{(m)} e_t + \sum_{t=1}^{m} e_{t-1}^{(m)^2}.
\]

Note that, unlike $RV_i^{*}(m)$, $u_i^{(m)}$ is not necessarily positive because the first term of $u_i^{(m)}$ may be negative. We call $u_i^{(m)}$ an MN component. We propose a way of estimating the MN component as well as the IV in a later section.

In Appendix A, we show that:
\[
E[u_i^{(m)}] = 2m\sigma_\varepsilon^2 \quad \text{and} \quad \text{cov}[u_i^{(m)}, u_s^{(m)}] = \begin{cases} 8\sigma_\varepsilon^2 \sigma_\varepsilon^2 + 2(2m - 1)\omega_\varepsilon^2 + 4m\sigma_\varepsilon^4, & t = s, \\ \omega_\varepsilon^2, & t = s + 1, \\ 0, & \text{otherwise}. \end{cases}
\]

Thus, $u_i^{(m)}$ has the autocovariance structure of a MA(1) process. Assume that the MA(1) process is expressed as:
\[
u_i^{(m)} = \xi_i^{(m)} + \xi_i^{(m)} + \theta_u^{(m)} \xi_{i-1}^{(m)}, \quad \xi_i^{(m)} \sim WN(0, \sigma_\xi^2(m)),
\]
where $WN(0, a)$ denotes a white noise process with variance $a$. The mean and autocovariances of $u_i^{(m)}$, in terms of $\sigma_u^{(m)}$, $\theta_u^{(m)}$ and $\sigma_\xi^2(m)$, are:
\[
E[u_i^{(m)}] = \sigma_u^{(m)} \quad \text{and} \quad \text{cov}[u_i^{(m)}, u_s^{(m)}] = \begin{cases} (1 + \theta_u^{(m)})\sigma_\xi^2(m), & t = s, \\ \sigma_u^{(m)} \sigma_\xi^2(m), & t = s + 1, \\ 0, & \text{otherwise}. \end{cases}
\]

Later, we utilize these two different expressions of the moments of $u_i^{(m)}$ to derive the implicit relationships among the SV and MA(1) process parameters.

### 3 ARMA Representation of IV

In this section, we briefly summarize the results in Meddahi (2003) on an ARMA representation of IV for SR-SARV models.
3.1 One–factor case

Meddahi (2003, Proposition 3.1) shows that if the true process of \( p(t) \) follows a one–factor SR–SARV model, then \( IV_t \) follows an ARMA(1, 1) process:

\[
IV_t = c_{IV} + \kappa_1 IV_{t-1} + \eta_t + \theta_1 \eta_{t-1},
\]

where \( \kappa_1 \) is defined as in the statement below (2), \( \eta_t \) is a white noise process with \( \text{var}(\eta_t) = \sigma^2_\eta \) and \( \text{cov}(\eta_t, d_s^{(m)}) = 0 \) for all \( t \) and \( s \). Other ARMA(1, 1) model parameters \( c_{IV}, \theta_1 \) and \( \sigma^2_\eta \) are expressed in terms of the one–factor SR–SARV model parameters \( \sigma^2, \omega^2, \) and \( \kappa_1 \) as:

\[
c_{IV} = (1 - \kappa_1)\sigma^2, \quad \theta_1 = \frac{1 - \sqrt{1 - 4\rho^2}}{2\rho}, \quad \sigma^2_\eta = \frac{(1 + \kappa_1^2)\text{var}(IV_t) - 2\kappa_1\text{cov}(IV_t, IV_{t-1})}{1 + \theta_1^2}, \tag{11}
\]

where

\[
\rho \equiv \frac{-\kappa_1 + \text{corr}[IV_t, IV_{t-1}]}{1 + \kappa_1^2 - 2\kappa_1\text{corr}[IV_t, IV_{t-1}]}. \tag{12}
\]

It can be shown that \( \rho \) is equal to \( \theta_1/(1 - \theta_1^2) \), i.e., the first order autocorrelation of the MA(1) process \( \eta_t + \theta_1 \eta_{t-1} \) in (10). The \( \text{corr}[IV_t, IV_{t-1}] \) is given by

\[
\text{corr}[IV_t, IV_{t-1}] = \frac{(1 - \kappa_1)^2}{2(\kappa_1 - \log \kappa_1 - 1)}.
\]

Note that \( \text{corr}[IV_t, IV_{t-1}] \) is a function of \( \kappa_1 \) and does not depend on other SV model parameters, which, in turn, implies that \( \theta_1 \) is also a function of only \( \kappa_1 \). This is not true for the two-factor case. This substantially simplifies the identification problem of the state space form of the NCRV, as we will see in Section 4.

3.2 Two–factor case

Meddahi (2003, Proposition 3.3) shows that if the true process of \( p(t) \) belongs to the two–factor SR–SARV model, then \( IV_t \) follows an ARMA(2, 2) process:

\[
IV_t = c_{IV} + (\kappa_1 + \kappa_2) IV_{t-1} - \kappa_1 \kappa_2 IV_{t-2} + \eta_t + \theta_1 \eta_{t-1} + \theta_2 \eta_{t-2}, \tag{12}
\]

where \( \kappa_1 \) and \( \kappa_2 \) are defined as in the statement below Equation (2), \( \eta_t \) is a white noise process with \( \text{var}(\eta_t) = \sigma^2_\eta \) and \( \text{cov}(\eta_t, d_s^{(m)}) = 0 \) for all \( t \) and \( s \). Let \( \phi_1 = \kappa_1 + \kappa_2 \) and \( \phi_2 = -\kappa_1 \kappa_2 \). Other ARMA(2, 2) model parameters in (12) \( c_{IV}, \theta_1, \theta_2 \) and \( \sigma^2_\eta \) are expressed in terms of the two–factor SR–SARV model parameters \( \sigma^2, \omega^2, \kappa_1 \) and \( \kappa_2 \) as:

\[
c_{IV} = (1 - \phi_1 - \phi_2)\sigma^2, \quad \theta_1 = \frac{1 - \sqrt{4s + 1} \rho_1}{2 \rho_2}, \quad \theta_2 = \frac{\sqrt{4s + 1} - 2s - 1}{2s}, \quad \sigma^2_\eta = \frac{\pi_1 \text{var}(IV_t) - 2\pi_2 \text{cov}(IV_t, IV_{t-1}) - 2\phi_2 \text{cov}(IV_t, IV_{t-2})}{1 + \theta_1^2 + \theta_2^2}, \tag{13}
\]

We can rewrite the ARMA(2, 2) form in (12) with a more familiar parameterization, i.e., \( IV_t = c_{IV} + \phi_1 IV_{t-1} + \phi_2 IV_{t-2} + \eta_t + \theta_1 \eta_{t-1} + \theta_2 \eta_{t-2} \). The expressions of \( \kappa_1 \) and \( \kappa_2 \) in terms of \( \phi_1 \) and \( \phi_2 \) are given as \( \kappa_1 = \frac{\phi_1 + \sqrt{\phi_1^2 + 4\phi_2}}{2} \), and \( \kappa_2 = \frac{\phi_1 - \sqrt{\phi_1^2 + 4\phi_2}}{2} \), respectively.
where
\[
\pi_1 = 1 + \phi_1^2 + \phi_2^2, \quad \pi_2 = \phi_1(1 - \phi_2),
\]
\[
s \equiv -\frac{\rho_2^2}{\rho_1^2} \left[ 1 + \frac{1}{2\rho_2} - \text{sign}(\rho_2) \sqrt{\left( 1 + \frac{1}{2\rho_2} \right)^2 - \frac{\rho_2^2}{\rho_1^2}} \right],
\]
\[
\rho_1 \equiv \frac{\phi_1(1 - \phi_2) + (1 + \phi_1^2 - \phi_2) \text{corr}[IV_i, IV_{i-1}]}{(1 + \phi_1^2 + \phi_2^2) - 2\phi_1(1 - \phi_2) \text{corr}[IV_i, IV_{i-1}] - 2\rho_2 \text{corr}[IV_i, IV_{i-2}]}, 
\]
\[
\rho_2 \equiv \frac{-\phi_2 - \phi_1 \text{corr}[IV_i, IV_{i-1}] + \text{corr}[IV_i, IV_{i-2}]}{(1 + \phi_2^2 + \phi_1^2) - 2\phi_1(1 - \phi_2) \text{corr}[IV_i, IV_{i-1}] - 2\rho_2 \text{corr}[IV_i, IV_{i-2}]},
\]
and \( \text{sign}(\rho_2) = 1 \) if \( \rho_2 > 0 \) and \( \text{sign}(\rho_2) = -1 \) if \( \rho_2 < 0 \). We assume that \( \rho_2 \neq 0 \), which implies that \( \theta_2 \neq 0 \). As in the one-factor case, we can show that \( \rho_1 = (\theta_1 + \theta_2)/(1 + \theta_1^2 + \theta_2^2) \) and \( \rho_2 = \theta_2/(1 + \theta_1^2 + \theta_2^2) \), i.e., \( \rho_1 \) and \( \rho_2 \) are the first and second order autocorrelations of the MA(2) process \( \eta_t + \theta_1 \eta_{t-1} + \theta_2 \eta_{t-2} \) in (12), respectively. See Meddahi (2002) and Meddahi (2003) for more details.

4 State Space Approach

In this section, we explain our state space approach in detail. Our state space approach is in the same spirit as the state space method used in Barndoff-Nielsen and Shephard (2002), who consider the situation without MN. First, we give a state space form of the NCRV in Section 4.1. The existence of MN components requires additional efforts for checking the identification of the state space form. In Section 4.2, we show that the state space form parameters are not identifiable; however, they can be expressed as functions of fewer identifiable parameters. We illustrate how to estimate these identifiable parameters in Section 4.3.

In what follows, we assume that \( \omega_2 = 0 \) for ease of exposition. Corresponding results for the two-factor case can be derived in a similar manner and are summarized in the Appendix B.

4.1 State space form of the NCRV

Substituting \( RV_i^{(m)} = IV_i + d_i^{(m)} \) into (6), we have:
\[
RV_i^{(m)} = IV_i + d_i^{(m)} + u_i^{(m)}. 
\]  
(15)

Let \( \eta_t \) and \( \xi_t^{(m)} \) be denoted by the state variables \( \alpha_t \) and \( \beta_t^{(m)} \), respectively. From (8), (10) and (15), we have the following state space form of \( RV_i^{(m)} \):

**Observation equation**

\[
RV_i^{(m)} = \begin{bmatrix} 1 & 1 & 0 & 0 \end{bmatrix} \begin{bmatrix} \eta_t \\ u_i^{(m)} \\ \alpha_t \\ \beta_t^{(m)} \end{bmatrix} + d_i^{(m)}, 
\]  
(16a)

**State equation**

\[
\begin{bmatrix} IV_i \\ u_i^{(m)} \\ \alpha_t \\ \beta_t^{(m)} \end{bmatrix} = \begin{bmatrix} c_{IV} \\ c_t^{(m)} \\ 0 \\ 0 \end{bmatrix} + \begin{bmatrix} \kappa_t & 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} \eta_t \\ \theta_t^{(m)} \end{bmatrix} + \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} IV_{i-1} \\ u_{i-1}^{(m)} \\ \alpha_{t-1} \\ \beta_{t-1}^{(m)} \end{bmatrix} + \begin{bmatrix} \xi_t^{(m)} \end{bmatrix}, 
\]  
(16b)
where
\[
\begin{bmatrix}
\tilde{d}^{(m)}_t \\
\eta_t \\
\xi_t^{(m)}
\end{bmatrix}
\sim
\begin{bmatrix}
0 \\
0 \\
0
\end{bmatrix},
\begin{bmatrix}
\sigma^2_{\eta} \\
\sigma^2_{d} \\
\sigma^2_{\xi}
\end{bmatrix}.
\] (16c)

Given the values of \(c_{IV}, \kappa_1, \theta_1, \sigma^2_{\eta}, \sigma^2_{d}, \sigma^2_{\xi}, \theta_u^{(m)}, \sigma^2_u^{(m)}\) and \(\sigma^2_d^{(m)}\), we can estimate \(IV_t^{(m)}\) and \(u_t^{(m)}\) by applying the Kalman filter to the state space form.\(^3\) One problem of the state space form is how to estimate those parameters. One may simply think that we could estimate them directly from the state space form by, for example, quasi-maximum likelihood (QML) estimation under Gaussian noise assumption. We show, however, that this approach is not applicable for the state space form given in (16a) – (16c).

In general, parameters of a state space form are not necessarily identified (see, for example, Hamilton, 1994, p.388). More precisely, they are not identified in the sense that there are infinitely many combinations of the parameters that give the same autocovariance structure. Thus, we have to check whether state space form parameters are uniquely identified before proceeding to their estimation. We consider this problem in the next subsection. In fact, we show that the above parameters in the state space form cannot be uniquely identified.

### 4.2 Identification of model parameters

Because \(RV_t^{(m)}\) is the sum of three components, \(IV_t^{(m)}\) (an ARMA(1, 1) process), \(d_t^{(m)}\) (a white noise process) and \(u_t^{(m)}\) (an MA(1) process), \(RV_t^{(m)}\) itself follows an ARMA(1, 2) process (see Granger and Morris, 1976) so that it is expressed as:

\[
(1 - \kappa_1 L)RV_t^{(m)} = c_{RV}^{(m)} + (1 + \delta_1^{(m)} L + \delta_2^{(m)} L^2)\tau_t^{(m)} , \quad \tau_t^{(m)} \sim WN(0, \sigma^2_{\tau}^{(m)}).
\] (17)

Note that the AR coefficient \(\kappa_1\) is the same as that of the \(IV_t\) in (10). The ARMA model representation of a state space form is commonly referred to as a reduced form or ARMA reduced form. Parameters of the ARMA reduced form are identifiable.

From (8), (10) and (15), we have

\[
(1 - \kappa_1 L)RV_t^{(m)} = (1 - \kappa_1 L)IV_t^{(m)} + (1 - \kappa_1 L)d_t^{(m)} + (1 - \kappa_1 L)u_t^{(m)}
\]
\[
= c_{IV} + \eta_t + \theta_1 \eta_{t-1} + d_t^{(m)} - \kappa_1 d_{t-1}^{(m)} + \xi_t^{(m)}
\]
\[
+ (1 - \kappa_1)\eta_t^{(m)} + (\theta_u^{(m)} - \kappa_1)\xi_{t-1}^{(m)} - \kappa_1 \theta_u^{(m)} \xi_{t-2}^{(m)}.
\] (18)

The two expressions on the right-hand sides in (17) and (18) are of the same process and hence their means and autocovariances must be identical. The autocovariances of the MA process in (17) are given as

\[
\begin{align*}
\gamma_0^{(m)} &= (1 + \delta_1^{(m)} + \delta_2^{(m)} L^2)\sigma^2_{\tau}^{(m)} , \\
\gamma_1^{(m)} &= (\delta_1^{(m)} + \delta_2^{(m)} L^2)\sigma^2_{\tau}^{(m)} , \\
\gamma_2^{(m)} &= \delta_2^{(m)} L^2\sigma^2_{\tau}^{(m)} , \\
\mathbf{\gamma}_j^{(m)} &= 0 \text{ for } j \geq 3,
\end{align*}
\] (19)

It is shown in the Appendix A that the autocovariances of the MA process in (18) are

\[
\begin{align*}
\gamma_0^{(m)} &= (1 + \delta_1^{(m)} L^2 + \delta_2^{(m)} L^4)\sigma^2_{\tau}^{(m)} [1 + (\theta_u^{(m)} - \kappa_1)^2 + \kappa_1^2 \theta_u^{(m)2}]\sigma^2_{\xi}^{(m)} , \\
\gamma_1^{(m)} &= \theta_1 \sigma^2_{\eta} - \kappa_1 \sigma^2_{\xi}^{(m)} + (\theta_u^{(m)} - \kappa_1)\sigma^2_{\xi}^{(m)} , \\
\gamma_2^{(m)} &= -\kappa_1 \theta_u^{(m)} \sigma^2_{\xi}^{(m)} ,
\end{align*}
\] (20a-c)

\(^3\)Note that here \(\eta_t\) and \(\xi_t\) do not follow a Gaussian distribution. In this case, the Kalman filter provides the best linear unbiased estimator (Andersen and Moore, 1979). See Durbin and Koopman (2001) for more details on the Kalman filter.
and \( \gamma_j = 0 \) for \( j \geq 3 \). By equating the means of the MA processes in (17) and (18), we have

\[
\epsilon_{RV}^{(m)} = c_{IV} + (1 - \kappa_1)c_u^{(m)}. \tag{20d}
\]

Given the ARMA(1, 2) model parameters, \( \epsilon_{RV}^{(m)} \), \( \kappa_1, \delta_1, \delta_2 \) and \( \sigma^2 \), we can calculate \( \gamma_j^{(m)} \), \( j = 0, 1, 2 \). Then, unknown parameters in the equations (20a)~(20d) are only the state space form parameters, \( c_{IV}, \theta_1, \sigma_u^2, c_u^{(m)}, \theta_u^{(m)}, \sigma_z^{(m)} \) and \( \sigma_d^{(m)} \). Observe that there are seven unknown parameters and only four equations. Hence, we cannot uniquely identify these parameters from these equations. In other words, for a given ARMA(1, 2) reduced form, there are infinitely many sets of values of \( c_{IV}, \theta_1, \sigma_u^2, c_u^{(m)}, \theta_u^{(m)}, \sigma_z^{(m)} \) and \( \sigma_d^{(m)} \) that give the same autocovariance structure as the ARMA(1, 2) reduced form.

In view of (7) and (9), we obtain the following equations:

\[
c_u^{(m)} = 2m\sigma_z^2, \tag{21a}
\]

\[
(1 + \theta_u^{(m)})\sigma_z^{(m)} = 8\sigma^2 \sigma_z^2 + 2(2m - 1)\omega_2^2 + 4m\sigma_z^4, \tag{21b}
\]

\[
\theta_u^{(m)} \sigma_z^{(m)} = \omega_2^2. \tag{21c}
\]

Assuming that the MA parameter satisfies the invertibility condition, i.e., \( |\theta_u^{(m)}| < 1 \), we can solve the equations (21a) ~ (21c) for \( c_u^{(m)}, \theta_u^{(m)} \) and \( \sigma_z^{(m)} \) as:

\[
c_u^{(m)} = 2m\sigma_z^2, \quad \sigma_z^{(m)} = \frac{\omega_2^2}{\theta_u^{(m)}} \quad \text{and} \quad \theta_u^{(m)} = A - \sqrt{A^2 - 1}, \tag{22}
\]

where \( A = 4\sigma^2 \sigma_z^4 + 2m - 1 + 2m\frac{\sigma_z^2}{\omega_2^2} \). The details of the calculation is given in the Appendix A.

Note that \( 0 < \theta_u^{(m)} < 1 \) because \( A > 1 \).

From (3), (11) and (22), we see that \( c_{IV}, \theta_1, \sigma_u^2, c_u^{(m)}, \theta_u^{(m)}, \sigma_z^{(m)} \) and \( \sigma_d^{(m)} \) are expressed as functions of \( \kappa_1, \sigma^2, \omega_1^2, \sigma_z^2 \) and \( \omega_z^2 \). To emphasize these relationships, we denote them as:

\[
c_{IV}(\kappa_1, \sigma^2), \quad \theta_1(\kappa_1), \quad \sigma_u^2(\kappa_1, \omega_1^2), \quad c_u^{(m)}(\sigma_z^2), \quad \theta_u^{(m)}(\sigma^2, \sigma_z^2, \omega_z^2),
\]

\[
\sigma_d^{(m)}(\kappa_1, \sigma^2, \omega_1^2) \quad \text{and} \quad \sigma_z^{(m)}(\sigma^2, \sigma_z^2, \omega_z^2). \tag{23}
\]

Note that \( \theta_1 \) is a function of only \( \kappa_1 \) and hence can be assumed to be known (because \( \kappa_1 \) is identified from the reduced form). Substituting the expressions in (23) into Equations (20a)~(20d), we have four equations for the four unknown parameters \( \sigma^2, \omega_1^2, \sigma_z^2 \) and \( \omega_z^2 \). Hence, the order condition for identification is satisfied. However, this result does not imply that one can uniquely identify \( \sigma^2, \omega_1^2, \sigma_z^2 \) and \( \omega_z^2 \).

To show the uniqueness of the identification, we explicitly derive the representations of \( \sigma^2, \omega_1^2, \sigma_z^2 \) and \( \omega_z^2 \) in terms of \( c_{IV}^{(m)}, \kappa_1, \gamma_j^{(m)}, j = 0, ..., 2 \). In Appendix A, we show that, given \( c_{IV}^{(m)}, \kappa_1, \gamma_j^{(m)}, j = 0, ..., 2 \), Equations (23) are uniquely solved for \( \sigma^2, \omega_1^2, \sigma_z^2 \) and \( \omega_z^2 \) as:

\[
\omega_2^2 = \frac{-\gamma_2^{(m)}}{\kappa_1}, \quad \omega_z^2 = \frac{(\log \kappa_1)\gamma_0^{(m)} + (1 + \kappa_1^2)\gamma_1^{(m)} + \frac{1 + \kappa_1^2}{\kappa_1} \gamma_2^{(m)}}{(1 - \kappa_1)^3(1 + \kappa_1)}, \tag{24a}
\]

\[
\sigma_z^2 = \sqrt{\frac{c_{IV}^{(m)} - (2m - 1)\gamma_2^{(m)}}{2m\kappa_1(1 - \kappa_1)^2} - \frac{\gamma_0^{(m)} - 2\omega_1^2 - 2\gamma_2^{(m)}}{4m(1 + \kappa_1^2)}}, \tag{24b}
\]

\(^4\text{They depend also on } m \text{ as the notation implies.}\)

\(^5\text{More precisely, under the condition } \sigma_z^2 > 0.\)
and
\[
\sigma^2 = \frac{c_{RV}^{(m)}}{1 - \kappa_1} - 2m\sigma_z^2, \quad \text{where} \quad D = B + m(1 + \kappa_1^2)C,
\]  \hspace{1cm} (24c)
\[
B \equiv \frac{\kappa_1^2 - 1 - (1 + \kappa_1^2)\log \kappa_1}{(\log \kappa_1)^2} \quad \text{and} \quad C \equiv \frac{2\left(\kappa_1^2 - 1 - \log \kappa_1^2\right)}{(\log \kappa_1)^2}. \hspace{1cm} (24d)
\]
These results imply that the four parameters, \(\sigma^2, \omega_z^2, \sigma_z^2\) and \(\omega^2_z\) are uniquely identified from the ARMA(1, 2) reduced form in (17). Hence, in principle, we can estimate them. Again, it should be emphasized that these results do not imply that one can directly estimate the state space form parameters but rather that one can estimate the above four parameters by replacing the state space form parameters with the functions of the four parameters. The estimates of the state space form parameters are obtained by substituting the estimates of the four parameters into these functions.

4.3 Estimation of model parameters
We illustrate how to estimate the four parameters. There are two possible approaches: direct and indirect. Below, we illustrate first the indirect and then the direct approach. In both approaches, we apply QML estimation assuming Gaussian innovations.

We showed in (24) that these four parameters have explicit expressions in terms of the ARMA(1, 2) reduced form parameters. This suggests the following indirect approach for estimating these four parameters:

**Summary of the indirect approach**

**Step 1** For a given \(m\), calculate \(RV_t^{\ast(m)}\).

**Step 2** Estimate the unrestricted ARMA(1, 2) model in (17) by QML estimation assuming Gaussian innovations.

**Step 3** Given the estimates of \(c_{RV}^{(m)}, \kappa_1, \delta_1^{(m)}, \delta_2^{(m)}\) and \(\sigma_z^2\) obtained in Step 2, calculate the first three autocovariances of the MA process, namely, \(\gamma_j^{(m)}, j = 0 \sim 2\) as in (19).

**Step 4** Given the estimates of \(c_{RV}^{(m)}, \kappa_1\) and \(\gamma_j^{(m)}, j = 0 \sim 2\) obtained in Steps 2 and 3, estimate \(\omega_z^2, \sigma_z^2, \omega^2_z\) and \(\sigma^2\) applying the results in (24a) – (24d).

This approach is simple and easy to implement; however, it does not guarantee that the resulting parameter estimates are positive because of the inevitable uncertainty of the ARMA model estimation. For example, if \(\gamma_2^{(m)} > 1\), then the estimate of \(\omega^2_z\) by this approach is negative because \(\kappa_1 > 0\) by assumption.

Alternatively, one can directly estimate these four parameters. In this approach, one calculates the log-likelihood directly from the four parameters and maximizes it with respect to the four parameters. Thus, we can easily impose the positivity of the four parameters. Below, we summarize how to obtain the QML estimates by this approach.

**Summary of the direct approach**

**Step 1** For a given \(m\), calculate \(RV_t^{\ast(m)}\).

**Step 2** Given \(\kappa_1, \sigma^2, \omega^2_z, \sigma_z^2\) and \(\omega^2_z\), calculate \(c_{IV}, \theta_1, \sigma_\xi^2, c_{u}^{(m)}, \theta_\xi^{(m)}, \sigma_\xi^{2(m)}\) and \(\sigma_d^{2(m)}\) according to (3), (11) and (22).

**Step 3** With the \(c_{IV}, \theta_1, \sigma_\xi^2, c_{u}^{(m)}, \theta_\xi^{(m)}, \sigma_\xi^{2(m)}\) and \(\sigma_d^{2(m)}\) obtained in Step 2, calculate the Gaussian log-likelihood of the state space form given in (16a)–(16c) for \(RV_t^{\ast}\).
Step 4 Maximize the log-likelihood obtained in Step 3 with respect to the five parameters $\kappa_1, \sigma^2_e, \omega^2_p$, $\sigma^2_e$ and $\omega^2_{e}$ to obtain the QML estimates.

This approach provides consistent estimators for the four parameters.

Before closing this section, it should be noted that if we can obtain estimates properly by the indirect approach, we do not need to proceed to the direct approach, because both approaches will give the identical estimates in this case.

5 Empirical Analysis

In this section, we conduct an empirical analysis with exchange rate data using the proposed state space method.

5.1 Data description

The yen/dollar spot exchange rate series we use are the mid-quote prices observed every one minute, which are obtained from Olsen and Associates. The full sample covers the period from January 1, 2000 to December 31, 2006. Figure 1 plots the daily returns calculated from the price data over the period.

Price data are not available for each minute. When price data are missing we apply the previous tick method, i.e., we interpolate the most recent observed price. Furthermore, following Andersen, Bollerslev, Diebold and Labys (2001), we remove the data of inactive trading days. Whenever we do so, we always remove from 21:01 GMT on one night to 21:00 the next evening. For details on the motivation behind this definition of “day”, see Andersen, Bollerslev, Diebold and Labys (2001), Andersen and Bollerslev (1998) and Bollerslev and Domowitz (1993). We cut the data according to the following criteria, which are similar to the criteria adapted in Beine et al. (2007).

Specifically, we cut

(1) the days where there are more than 500 missing price observations,

(2) the days where, in total, there are more than 1000 minutes of zero returns

(3) the days where the price does not change for more than 35 minutes.

By these criteria, we could remove all weekend data. However, the days such as US holidays that Andersen, Bollerslev, Diebold and Labys (2001) and Beine et al. (2007) remove are not necessarily removed by these criteria. This is because even when the US market is closed, transactions are made in other markets. Eventually, we are left with 1809 complete days, or $1809 \times 1440 = 2604960$ price observations, from which we calculate the one-minute and five-minute returns.

With these returns, we calculate two series of daily NCRV, namely, one-minute NCRV ($m = 1440$) and five-minute NCRV ($m = 288$). Table 1 reports the descriptive statistics of these two series of NCRV, and Figure 2 plots them. The sample mean of the one-minute NCRV is greater than that of the five-minute NCRV. This is consistent with the existence of MN because the mean of the NCRV increases as the sampling frequency increases, or $m \rightarrow \infty$ under the existence of MN (see (20d) and (21a)). The first order autocorrelations of these two series of NCRV are somewhat lower than usually expected for variances of financial time series: they are 0.4794 for the one-minute NCRV and 0.4177 for the five-minute NCRV. This may be because of the existence of MN. In fact, in the next subsection, we show that estimates of the first order autocorrelation of the IV are significantly higher than these values.

5.2 Estimation of parameters, IV and MN component

For these two series of the NCRV, we estimate the parameters of the one- and two-factor SV models by the method described in Section 4.3 (and in Appendix B for the two-factor case). Note that, in general, the values of these two NCRV series are different although they both are
estimates of the same IV series. Consequently, the estimates of the SV model parameters are
different, depending on which NCRV series is used. We report only the results by the direct
approach because the indirect approach does not provide positive variance estimates. Table 2
displays the estimates of the SV model parameters. Naturally, the estimated values of the SV
model parameters for one-minute and five-minute NCRV series are very similar. In both the one-
and two-factor cases, estimates with the five-minute NCRV series are slightly more efficient than
those with the one-minute NCRV series according to the robust standard errors. The estimates
of the persistence parameters for two-factor SV model (i.e., \( \hat{\kappa}_1 \) and \( \hat{\kappa}_2 \)) imply that there are
two factors with significantly different levels of persistence. One of them is very persistent and
the other is moderately persistent, although their unconditional variances are not significantly
different. For the one-factor SV model, the persistence of these two factors must be captured by
only one parameter, \( \kappa_1 \). As a result, the estimate of \( \kappa_1 \) in the one-factor case is somewhat lower
than that in the two-factor case.

The estimates of state space form parameters in (16) (and in (40) for the two-factor case) are
computed from the estimates of the SV model parameters. They are shown in Table 3. Again, the
estimates of the common parameters, which do not depend on \( m \), are very similar. We find that
the estimates of the mean of the MN component, denoted by \( \hat{\mu}_0^{(m)} \), in one-minute NCRV series
is greater than that in five-minute NCRV series, which implies that the one-minute NCRV series has
a larger bias than the five-minute NCRV series. This is consistent with the theory. The magnitude
of bias of the one-minute NCRV is about four times larger than that of the five-minute NCRV.

Table 4 reports the estimates of some important values including the autocorrelations of the
IV. In both the one- and two-factor cases, the estimates of the first order autocorrelation of IV are
significantly higher than those of the two NCRV series. This result suggests that the existence
of MN lowers the autocorrelations of the NCRV series. The estimates of the ratio of the unconditional
variance of the MN component to the unconditional variance of the NCRV imply that a half
of the aggregate fluctuations of the NCRV series is because of the MN component.

We display the estimates of the IV series by Kalman smoothing for the five-minute and one-
minute NCRV series in Figures 3(a) and (b), respectively. Figure 3(c) is the difference between
them, or \( \hat{IV}_t^{(1440)} - \hat{IV}_t^{(288)} \), where \( \hat{IV}_t^{(m)} \) is the estimate of \( IV_t \) with a given \( m \). Note that these
estimates are the estimates of the same IV series and thus are very similar. The IV estimates in the
one-factor case seem smoother than those in the two-factor case. This is because of the result that the (estimated) autocorrelations of the IV series are lower for the two-factor case and thus they are
relatively closer to white noise compared with the IV series obtained for the one-factor case. Figure
4 (a), (b) and (c) plot the smoothed estimates of the five-minute and one-minute NCRV component
series and their differences, respectively. We can see that the MN component occasionally takes a
large value. Figure 5 (a) and (b) display the estimates of the discretization errors by Kalman
smoothing for five-minute and one-minute NCRV, respectively. The discretization error estimates
for the one-minute NCRV series is quite small than those for the five-minute NCRV series, which
is again consistent with the theoretical result. Corresponding figures for the two-factor case are
given in Figures 6–8. They are very similar to these for the one-factor case.

Finally, we calculate the ratios of the MN component to the NCRV \( \hat{R}(m) \). They are given by
\( \hat{R}^{(m)} = \frac{\hat{u}_t^{(m)}}{RV_t^{(m)}}, t = 1, \ldots, 1809 \), where \( \hat{u}_t^{(m)} \) is the estimate of \( u_t^{(m)} \) by Kalman smoothing.

The results are shown in Table 5. In the one-factor (two-factor) case, the maximum and minimum
values of \( \hat{R}(m) \) are, respectively, 0.8324 (0.6574) and -0.5804 (-3.7323) for the five-minute NCRV
series and 0.8357 (1.0454) and -0.5804 (-0.4192) for the one-minute NCRV series. We also
calculate the average magnitude of the MN component as the mean of \( |R^{(m)}(\bar{m})| \) (the average of \( R^{(m)} \)

\(^{6}\)To obtain the QML estimates of the SV model parameters, first, we calculate the QML estimates of the transformed ones, such as \( \hat{\mu} \equiv \log(\hat{\sigma}^2) \), by applying an unconstrained maximization procedure. Then, the QML estimate of, for example, \( \sigma^2 \) is obtained by \( \log(\hat{\mu}) \), where \( \hat{\mu} \) is the QML estimate of \( \mu \). The robust standard errors of the SV model parameter estimates are calculated as follows. First, generate samples from the asymptotic normal
distribution of the estimates of the transformed parameters (such as \( \hat{\mu} \)) with their robust asymptotic covariance matrix estimates (and the mean being set to the estimates). Next, for each sample, calculate the estimates of the SV model parameters. Lastly, calculate the sample standard deviations of these SV model parameter estimates, which are our robust standard errors.
is also reported in Table 5. In the one-factor (two-factor) case, the value of the mean is 0.4659 (0.2080) for the five-minute NCRV series and 0.4708 (0.4770) for the one-minute NCRV series. From these results, we conclude that the average magnitude of the MN component in the daily NCRV ranges from 21% to 48% of NCRV, depending on the sampling frequency.

6 Summary and Concluding Remarks

In this paper, we proposed a state space approach to estimating the IV and MN components simultaneously. Our method is based on the result in Meddahi (2003), who shows that when the true log-prices follow a general class of continuous-time SV models, the IV follows an ARMA process. We showed that under the existence of MN, the observed RV, or the NCRV, also follows an ARMA process. We represented the NCRV by a state space form and established the uniqueness of the identification of the state space form parameters. The proposed method was applied to yen/dollar exchange rate data, where we found that the NCRV calculated with five-minute returns is less biased than with one-minute returns. The two series of IV estimates by the proposed method with one-minute and five-minute returns are very similar. The method was also used for estimating the MN component.

In the estimation, we constructed the log-likelihood using only either the one-minute or five-minute NCRV series. It is more desirable to use both NCRV series for estimating the common parameters. It would be possible to obtain more efficient estimators by combining the one- and five-minute NCRV series. This is a subject for future research. It is also important to relax the assumption that there is no leverage effect in order to apply our method to stock return data.
Appendix A: Derivations of Equations

Hereafter, we suppress \( (m) \)’ in the notations \( r_i^{(m)}, u_i^{(m)} \) and \( e_i^{(m)} \), and let \( \varepsilon_t \) denote \( \varepsilon(t) \) for notational simplicity.

**Derivation of (7)**

Because \( \text{var}(e_t) = 2\sigma_e^2 \) and \( r_t \) is independent of \( e_t \) by Assumption 1, we have:

\[
E[u_t] = 2 \sum_{i=1}^{m} E \left[ r_{t-1+i, \frac{1}{m}} e_{t-1+i, \frac{1}{m}} \right] + \sum_{i=1}^{m} E \left[ e_{t-1+i, \frac{1}{m}}^2 \right] \\
= 2 \sum_{i=1}^{m} E \left[ r_{t-1+i, \frac{1}{m}} \right] E \left[ e_{t-1+i, \frac{1}{m}} \right] + m \text{var}(e_t) \\
= 2m\sigma_e^2.
\]

To derive \( \text{var}[u_t] \) and \( \text{cov}[u_t, u_{t-1}] \), we calculate \( \text{cov}[r_s e_s, r_t e_t] \) and \( \text{cov}[e_t^2, e_s^2] \). When \( t = s \), we have:

\[
\text{cov}[r_t e_t, r_t e_t] = E \left[ r_t^2 e_t^2 \right] - (E[r_t e_t])^2 \\
= E \left[ e_t^2 \right] E \left[ r_t^2 \right] - (E[r_t])^2 (E[e_t])^2 \\
= 2\sigma_e^2 \text{var}(e_t) \left( \int_{s-1/m}^{s} \sigma(s) dW(s) \right)^2 \\
= 2\sigma_e^2 \left( \int_{s-1/m}^{s} \sigma(s) ds \right)^2 \\
= \frac{2\sigma_e^2 \sigma_s^2}{m}.
\]

The fourth equality comes from the Ito isometry. When \( t \neq s \), we have:

\[
\text{cov}[r_s e_s, r_t e_t] = E \left[ r_s e_s r_t e_t \right] - E[r_s e_s] E[r_t e_t] \\
= E[e_s e_t] E[r_s] E[r_t] - E[r_s] E[e_s] E[r_t] E[e_t] \\
= 0.
\]

When \( t = s \), we have:

\[
\text{cov}[e_t^2, e_t^2] = \text{var}[e_t^2] \\
= E[e_t^4] - (E[e_t^2])^2 \\
= E \left[ e_t^4 - 4\sigma_e^2 e_t^2 + 6\sigma_e^2 e_t^2 + 4\sigma_e^2 e_t^2 - 4\sigma_e^2 e_t^2 - 4\sigma_e^2 e_t^2 \right] - 4\sigma_e^4 \\
= 2E[e_t^2] + 2\sigma_e^2 \\
= 2\sigma_e^2 + 4\sigma_e^2.
\]

When \( t = s \pm \frac{1}{m} \), we have:

\[
\text{cov} \left[ e_s^2, e_{s-\frac{1}{m}}^2 \right] = \text{cov} \left[ e_{s+\frac{1}{m}}^2, e_s^2 \right] \\
= \text{cov} \left[ e_{s+\frac{1}{m}}^2 - 2e_s e_{s-\frac{1}{m}} e_s + e_s^2, e_{s+\frac{1}{m}}^2 - 2e_s e_{s-\frac{1}{m}}^2 + e_{s-\frac{1}{m}}^2 \right] \\
= \text{var}[e_s^2] + \omega_s^2.
\]

When \( t = s \pm \frac{1}{m} \) for \( i \geq 2 \), we have \( \text{cov}[e_t, e_s] = 0 \). Furthermore, we have \( \text{cov}[r_i e_t, e_s^2] = 0 \) for any \( t \) and \( s \) because:

\[
\text{cov}[r_i e_t, e_s^2] = E[r_i e_t e_s^2] - E[r_i e_t] E[e_s^2] \\
= E[r_i] E[e_t e_s^2] - E[r_i] E[e_t] E[e_s^2] \\
= 0.
\]
From (25) ~ (28), we have:

\[
\text{var}[u_t] = \text{var} \left[ \frac{\sum_{i=1}^{m} r_{t-1+i} \delta^i e_{t-1+i} + \sum_{i=1}^{m} e_{t-1+i}}{\sum_{i=1}^{m} e_{t-1+i}} \right] \\
= 4 \text{var} \left[ \frac{\sum_{i=1}^{m} r_{t-1+i} \delta^i e_{t-1+i}}{\sum_{i=1}^{m} e_{t-1+i}} \right] + \text{var} \left[ \frac{\sum_{i=1}^{m} e_{t-1+i}^2}{\sum_{i=1}^{m} e_{t-1+i}} \right] + 4 \text{cov} \left[ \frac{\sum_{i=1}^{m} r_{t-1+i} \delta^i e_{t-1+i}}{\sum_{i=1}^{m} e_{t-1+i}}, \sum_{i=1}^{m} e_{t-1+i}^2 \right] \\
= 4 \sum_{i=1}^{m} \sum_{j=1}^{m} \text{cov} \left[ r_{t-1+i} \delta^i e_{t-1+i}, r_{t-1+j} \delta^j e_{t-1+j} \right] + \sum_{i=1}^{m} \sum_{j=1}^{m} \text{cov} \left[ e_{t-1+i}^2, e_{t-1+j}^2 \right] \\
+ 4 \sum_{i=1}^{m} \sum_{j=1}^{m} \text{cov} \left[ r_{t-1+i} \delta^i e_{t-1+i}, r_{t-1+j} \delta^j e_{t-1+j} \right] + \sum_{i=1}^{m} \sum_{j=1}^{m} e_{t-1+i}^2 \\
= 8 \sigma^2 \delta^2 + m(2 \omega^2 + 4 \sigma^4) + 2(m-1) \omega^2 \\
= 8 \sigma^2 \delta^2 + 2(2m-1) \omega^2 + 4m \sigma^4.
\]

and

\[
\text{cov}[u_t, u_{t+1}] = \text{cov} \left[ \frac{\sum_{i=1}^{m} r_{t-1+i} \delta^i e_{t-1+i} + \sum_{i=1}^{m} e_{t-1+i}^2}{\sum_{i=1}^{m} e_{t-1+i}} \right] \\
= 4 \text{cov} \left[ \frac{\sum_{i=1}^{m} r_{t-1+i} \delta^i e_{t-1+i}}{\sum_{i=1}^{m} e_{t-1+i}}, \sum_{i=1}^{m} e_{t-1+i}^2 \right] + 2 \text{cov} \left[ \frac{\sum_{i=1}^{m} r_{t-1+i} \delta^i e_{t-1+i}}{\sum_{i=1}^{m} e_{t-1+i}}, \sum_{i=1}^{m} e_{t-1+i}^2 \right] \\
+ \text{cov} \left[ \sum_{i=1}^{m} e_{t-1+i}^2, \sum_{i=1}^{m} e_{t-1+i}^2 \right] \\
\]

\[
\text{cov} = \omega^2.
\]

It is easy to check that \(\text{cov}[u_t, u_{t+i}] = 0\) for \(i \geq 2\), and hence we have (7).

**Derivation of (20a)~(20c)**

Here, we derive the autocovariances of the MA process in (18). They are given by

\[
\gamma_0 = \text{cov} \left[ \eta_0, \eta_0 \right] + \text{cov} \left[ \eta_0, \eta_0 \right] + \text{cov} \left[ \eta_0, \eta_0 \right] - \kappa_1 \eta_0 \xi_{-1} - \kappa_1 \eta_0 \xi_{-2}, \\
= \sigma^2 + \sigma^2 + \sigma^2 + \kappa^2 \sigma^2 - \kappa^2 \sigma^2 + \kappa^2 \sigma^2
\]

\[
= (1 + \kappa^2) \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2.
\]

\[
\gamma_1 = \text{cov} \left[ \eta_1, \eta_0 \right] + \text{cov} \left[ \eta_0, \eta_0 \right] - \kappa_1 \eta_0 \xi_{-1} + \kappa_1 \eta_0 \xi_{-2}, \\
= \sigma^2 + \sigma^2 + \sigma^2 + \kappa^2 \sigma^2 - \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2
\]

\[
= (1 + \kappa^2) \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2 + \kappa^2 \sigma^2
\]

Because it follows an MA(2) process, the autocovariances of the order greater than 2 is zero.

**Derivation of (22)**

From (21c), we have \(\sigma^2 = \omega^2/\theta_u\). Substituting this into (21b), we have:

\[
(1 + \theta_u^2 \omega^2 \sigma^2) = 8 \sigma^2 \sigma^2 + 2(2m-1) \omega^2 + 4m \sigma^4.
\]

Multiplying both sides by \(\theta_u/\omega^2\) and rearranging, we have:

\[
\theta_u - 2 \left[ \frac{4 \sigma^2 \sigma^2 + 2m - 1 + 2m \sigma^4}{\omega^2} \right] \theta_u + 1 = 0.
\]
The two solutions of this quadratic equation for \( \theta_u \) are given by
\[
\theta_u = A \pm \sqrt{A^2 - 1}, \quad \text{where} \quad A = \frac{4\sigma^2 \sigma_2^2}{\omega_2^2} + 2m - 1 + 2m \frac{\sigma_2^2}{\omega_2^2}.
\]

Because \( A > 1 \) for \( m \geq 1 \), we have \( A + \sqrt{A^2 - 1} > 1 \). Assuming that \( \theta_u \) satisfies the invertibility condition, we obtain \( \theta_u \) in (22).

**Derivation of (24a) and (24c)**

From (20c) and (21c), we have \( \omega_2^2 = -\frac{2a}{\kappa_1} \), which is the first result in (24a). From (3), (4) and (11), we have
\[
\sigma^2 = \frac{2B\omega_2^2}{1 + \theta_u^2} \quad \text{and} \quad \sigma_2^2 = \frac{2\sigma_2^4}{m} + 2m C \omega_1^2, \quad (29)
\]
where \( B \) and \( C \) are as given in (24d). From \( \omega_2^2 = \theta_u \sigma_2^2 \) in (21c), we have:
\[
(1 + \theta_u^2 - 2\theta_u \kappa_1 + \kappa_1^2 + \kappa_2 \theta_u^2) \sigma_2^2 = \left( \frac{1}{\theta_u^2} + \theta_u - \frac{\kappa_1}{\kappa_2} + \frac{\kappa_2}{\kappa_1} \theta_u \right) \omega_2^2
= \left[ \left( \frac{1}{\theta_u^2} + \theta_u \right) (1 + \kappa_1^2) - \frac{\kappa_1}{\kappa_2} \right] \omega_2^2, \quad (30)
\]
and
\[
(\theta_u - \kappa_1 - \kappa_2 \theta_u + \kappa_2 \theta_u) \sigma_2^2 = \left( \frac{1}{\theta_u^2} + \theta_u - \frac{\kappa_1}{\kappa_2} + \frac{\kappa_2}{\kappa_1} \theta_u \right) \omega_2^2
= \left[ 1 + \kappa_1^2 - \left( \frac{1}{\theta_u} + \theta_u \right) \kappa_1 \right] \omega_2^2. \quad (31)
\]
Substituting (29), (30) and (31) into (20a) and (20b), we have:
\[
\gamma_0 = 2D \omega_1^2 + 2 + \frac{\kappa_1^2}{m} \sigma_4^2 + \left( \frac{1}{\theta_u} + \theta_u \right) (1 + \kappa_1^2) - 2\kappa_1 \right] \omega_2^2, \quad (32a)
\]
and
\[
\gamma_1 = 2E \omega_1^2 - \frac{2\kappa_1}{m} \sigma_4^2 - \left[ \left( \frac{1}{\theta_u} + \theta_u \right) \kappa_1 - (1 + \kappa_1^2) \right] \omega_2^2, \quad (32b)
\]
where \( D = B + m(1 + \kappa_1^2)C \), \( E = \rho B - m \kappa_1 C \) and \( \rho = \theta_1/(1 - \theta_2^2) \). From (32), we have:
\[
\kappa_1 \gamma_0 + (1 + \kappa_1^2) \gamma_1 = 2 \left[ \kappa_1 D + (1 + \kappa_1^2) E \right] \omega_2^2 + \left[ (1 + \kappa_1^2) - 2\kappa_1 \right] \omega_2^2,
= 2 \left[ \kappa_1 + (1 + \kappa_1^2) \rho \right] B \omega_2^2 + (1 + \kappa_1^2) \omega_2^2,
= \frac{\left(1 - \kappa_1\right)^3}{(\log \kappa_1)^2} \left(1 + \kappa_1^2\right) \omega_2^2, \quad (33)
\]
where, to obtain the third equality, we use the alternative expression of \( \rho \) explained below (11). From (33), we have:
\[
\omega_2^2 = \frac{(\log \kappa_1)^2 \left[ \kappa_1 \gamma_0 + (1 + \kappa_1^2) \gamma_1 \right]}{\left(1 - \kappa_1\right)^3 (1 + \kappa_1)}
\]
Substituting \( \omega_2^2 = -\frac{2a}{\kappa_1} \), we obtain the second result in (24a). Next, note that from (22), we have:
\[
\frac{1}{\theta_u} + \theta_u = \frac{1 + \theta_u^2}{\theta_u}
= \frac{1 + (A - \sqrt{A^2 - 1})^2}{A - \sqrt{A^2 - 1}}
= \frac{A + \sqrt{A^2 - 1} + (A - \sqrt{A^2 - 1})^2 (A + \sqrt{A^2 - 1})}{(A - \sqrt{A^2 - 1})(A + \sqrt{A^2 - 1})}
= 2A. \quad (34)
\]
From (20d) and (21a), we have:

\[ c_{RV} = (1 - \kappa_1) \left( \sigma^2 + 2m\sigma^2_e \right), \quad \text{or} \quad \sigma^2_e = \frac{c_{RV} - (1 - \kappa_1)\sigma^2}{2(1 - \kappa_1)m}. \quad (35) \]

Substituting \( \sigma^2_e \) in (35) into \( A \) in (22), we have:

\[
2A = \left[ \frac{2e^{\sigma^2_e}}{(1 - \kappa_1)\sigma^2} - \frac{\sigma^4}{m\sigma^2_e} + 2m - 1 + \frac{2e^{\sigma^2_e}}{(1 - \kappa_1)\sigma^4} \right]^{\frac{1}{2}}
\]

\[
= 2 \left[ \frac{2e_{RV}\sigma^2}{(1 - \kappa_1)m\sigma^2_e} - \frac{\sigma^4}{m\sigma^2_e} + 2m - 1 + \frac{2e_{RV}\sigma^2}{(1 - \kappa_1)\sigma^4} \right]^{\frac{1}{2}}
\]

\[
= \frac{\frac{2e_{RV}\sigma^2}{(1 - \kappa_1)m\sigma^2_e} - \frac{\sigma^4}{m\sigma^2_e} + 2m - 1}{\left(1 - \kappa_1\right)^2} \quad \text{(36)}
\]

From (32a), (34) and (36), we have:

\[
\gamma_0 = 2D\omega^2 - \left(\frac{1 + \kappa_1^2}{m}\right)\sigma^4 + \frac{2(1 + \kappa_1^2)c_{RV}\sigma^2}{(1 - \kappa_1)m} + 2(2m - 1)(1 + \kappa_1^2)\omega^2 + \frac{2(1 + \kappa_1^2)c_{RV}^2}{(1 - \kappa_1)^2m} - 2\kappa_1\omega_e^2. \quad (37)
\]

Multiplying both sides in (37) by \( m/(1 + \kappa_1^2) \) and rearranging, we have:

\[
\sigma^4 - \frac{2e_{RV}}{1 - \kappa_1} \sigma^2 - \frac{c_{RV}^2}{(1 - \kappa_1)^2} + \frac{m}{1 + \kappa_1^2} \left( \frac{\gamma_0 - 2D\omega^2 + 2\kappa_1\omega^2}{1 + \kappa_1^2} \right) - 2m(2m - 1)\omega_e^2 = 0.
\]

Solving this quadratic equation for \( \sigma^2 \), we have:

\[
\sigma^2 = \frac{c_{RV}}{1 - \kappa_1} \pm \sqrt{\frac{2e_{RV}^2}{(1 - \kappa_1)^2} + 2m(2m - 1)\omega^2_e - m \left( \frac{\gamma_0 - 2D\omega^2 + 2\kappa_1\omega^2}{1 + \kappa_1^2} \right)} \quad (38)
\]

From \( \sigma^2 > 0, \kappa_1 < 1 \) and (35), we must have \( \frac{c_{RV}}{1 - \kappa_1} > \sigma^2 \). Hence, the sign of the second term in (38) is negative. From (35) and (38), we have:

\[
\sigma^2_e = \frac{1}{2m} \sqrt{\frac{2e_{RV}^2}{(1 - \kappa_1)^2} + 2m(2m - 1)\omega^2_e - m \left( \frac{\gamma_0 - 2D\omega^2 + 2\kappa_1\omega^2}{1 + \kappa_1^2} \right)} \quad (39)
\]

From (38) and (39), we obtain (24b) and (24c).
Appendix B: Results for the Two–factor Case

Let $\phi_1 = \kappa_1 + \kappa_2$, $\phi_2 = -\kappa_1 \kappa_2$, $\pi_1 = 1 + \phi_1^2 + \phi_2^2$, $\pi_2 = \phi_1(1 - \phi_2)$ and $\omega_2 \neq 0$ throughout Appendix B.

Let $\eta_t$ and $\xi_t$ be denoted by the state variables $\alpha_t$ and $\beta_t$, respectively. From (8), (12) and (15), we can express the NCRV in the following state space form:

**Observation equation**

\[
RV_t^* = \begin{bmatrix} 1 & 0 & 1 & 0 & 0 \end{bmatrix} + d_t, \tag{40a}
\]

**State equation**

\[
\begin{bmatrix}
IV_t \\
IV_{t-1} \\
u_t \\
\alpha_t \\
\alpha_{t-1} \\
\beta_t
\end{bmatrix} = \begin{bmatrix}
c_{IV} \\
0 \\
c_u \\
0 \\
0 \\
0
\end{bmatrix} \begin{bmatrix}
\phi_1 \\
\phi_2 \\
\theta_1 \\
\theta_2 \\
0 \\
0
\end{bmatrix} + \begin{bmatrix}
IV_{t-1} \\
IV_{t-2} \\
u_{t-1} \\
\alpha_{t-1} \\
\alpha_{t-2} \\
\beta_{t-1}
\end{bmatrix} + \begin{bmatrix}
1 \\
0 \\
0 \\
1 \\
0 \\
0
\end{bmatrix} \begin{bmatrix}
\eta_t \\
\xi_t
\end{bmatrix}, \tag{40b}
\]

where the mean vector and variance matrix of $(d_t, \eta_t, \xi_t)'$ are as given in (16c).

**Autocovariance functions**

In the two–factor case, by applying the results in Granger and Morris (1976), we can show that the NCRV follows an ARMA(2, 3) process:

\[(1 - \phi_1 L - \phi_2 L^2)RV_t^* = c_{RV} + (1 + \delta_1 L + \delta_2 L^2 + \delta_3 L^3)\eta_t, \quad \eta_t \sim WN(0, \sigma^2_\eta). \tag{41}\]

The same $RV_t^*$ can alternatively be expressed as:

\[(1 - \phi_1 L - \phi_2 L^2)RV_t^* = c_{RV} + \eta_t + \theta_1 \eta_{t-1} + \theta_2 \eta_{t-2} + d_t - \phi_1 d_{t-1} - \phi_2 d_{t-2} \]
\[+ (1 - \phi_1 - \phi_2) \xi_{t-2} + \xi_{t-3} - \phi_2 \xi_{t-3} \tag{42}\]

The autocovariance functions of the MA process in (41) are given as:

\[
\gamma_0 = (1 + \delta_1^2 + \delta_2^2 + \delta_3^2)\sigma^2_\eta, \quad \gamma_1 = (\delta_1 + \delta_2 \delta_3)\sigma^2_\eta, \tag{43a}
\]
\[
\gamma_2 = (\delta_2 + \delta_3 \delta_1)\sigma^2_\eta, \quad \gamma_3 = \delta_3 \sigma^2_\eta,
\]

and $\gamma_j = 0$, for $j \geq 4$. Furthermore, some calculations lead us to the following autocovariance functions of the MA process in (42):

\[
\gamma_0 = (1 + \theta_1^2 + \theta_2^2)\sigma^2_\eta + \pi_1 \sigma^2_\eta + \left[ \pi_1 \left( \frac{1}{\theta_u} + \theta_u \right) - 2\pi_2 \right] \theta_u \sigma^2_\xi, \tag{44a}
\]
\[
\gamma_1 = (\theta_1 + \theta_1 \theta_2)\sigma^2_\eta - \pi_2 \sigma^2_\eta + \left[ \pi_1 - \phi_2 - \pi_2 \left( \frac{1}{\theta_u} + \theta_u \right) \right] \theta_u \sigma^2_\xi, \tag{44b}
\]
\[
\gamma_2 = \theta_2 \sigma_n^2 - \phi_2 \sigma_d^2 - \left[ \phi_2 \left( \frac{1}{\theta_u} + \theta_u \right) + \pi_2 \right] \theta_u \sigma_\xi^2, \quad (44c)
\]

\[
\gamma_3 = -\phi_2 \theta_u \sigma_\xi^2, \quad (44d)
\]

and \( \gamma_j = 0, \) for \( j \geq 4. \) By equating the means of the MA processes on the right hand sides in (41) and (42), we obtain:

\[
c_{RV} = c_{IV} + (1 - \phi_1 - \phi_2)c_u. \quad (44e)
\]

As in the one-factor case, the number of state space form parameters is greater than the number of ARMA reduced form parameters. This implies that the state space form in (40) is not identified. However, we show that the state space form parameters are expressed as functions of the underlying continuous SV model parameters \( \sigma^2, \omega_1^2, \omega_2^2, \sigma_d^2 \) and \( \omega_\xi^2, \) which are uniquely identified from the ARMA reduced form in (41).

### Identification of state space form parameters

Here we show that the parameters \( \sigma^2, \omega_1^2, \omega_2^2, \sigma_d^2 \) and \( \omega_\xi^2 \) are uniquely identified from the reduced form parameters \( c_{RV}, k_1, k_2, \) and \( \gamma_j \) for \( j = 0 \sim 3. \)

As in the one-factor case, we can uniquely solve Equations (44a)-(44e) with respect to \( \sigma^2, \omega_1^2, \omega_2^2, \sigma_d^2 \) and \( \omega_\xi^2 \) as:

\[
\omega_\xi^2 = -\frac{\gamma_3}{\phi_2}, \quad \omega_1^2 = \frac{\left( \log k_1 \right)^2 \left[ (\alpha_1 \beta_0 - \alpha_0 \beta_1) - \kappa_2 (\alpha_1 \phi_1 + \alpha_2 \beta_0) \right]}{(1 - k_1) \left( k_1 - k_2 \right) (\alpha_1 \phi_1 - \alpha_2 \beta_1)}, \quad (45a)
\]

\[
\omega_2^2 = \frac{\left( \log k_2 \right)^2 \left[ (\alpha_1 \beta_0 - \alpha_0 \beta_1) - \kappa_1 (\alpha_1 \phi_1 + \alpha_2 \beta_0) \right]}{(1 - k_2) \left( k_2 - k_1 \right) (\alpha_1 \phi_1 + \alpha_2 \beta_1)}, \quad (45b)
\]

\[
\sigma_d^2 = \frac{1}{2m} \sqrt{\frac{2c_{RV}^2}{(1 - \phi_1 - \phi_2)^2} + 2m(2m - 1)\omega_1^2 + H}, \quad (45c)
\]

and

\[
\sigma = \frac{c_{RV}}{1 - \phi_1 - \phi_2} - 2m\sigma_d^2, \quad (45d)
\]

where

\[
\begin{align*}
\alpha_0 &= \pi_2 \gamma_0 + \pi_1 \gamma_1 - \left[ \pi_1 (1 - \phi_2) - \frac{\pi_1^2}{\phi_2} \right] \omega_2^2, \\
\alpha_1 &= \pi_1 (1 + \phi_1^2 - \phi_2) - 2\pi_2^2, \\
\alpha_2 &= 2\phi_2 \beta_2 + \phi_1 \beta_1, \\
\beta_0 &= \pi_2 \gamma_2 - \phi_2 \gamma_1 + (\phi_1^2 + \phi_2^2 - \phi_2) \omega_2^2, \\
\beta_1 &= \phi_2^2 - \phi_1^2 - \phi_2, \\
H &= \frac{m}{\phi_2} \left[ \gamma_2 + \sum_{j=1}^{2} (2\phi_2 C_{1,j} + \phi_1 C_{2,j} - C_{3,j} + 2m \phi_2 C_{4,j}) \omega_j^2 + \pi_2 \omega_2^2 \right], \quad (47)
\end{align*}
\]

\[
\begin{align*}
C_{1,j} &= \frac{\kappa_j - \log \kappa_j - 1}{(\log \kappa_j)^2}, \\
C_{2,j} &= \frac{(1 - \kappa_j)^2}{(\log \kappa_j)^2}, \\
C_{3,j} &= \frac{\kappa_j (1 - \kappa_j)^2}{(\log \kappa_j)^2}, \quad \text{and} \\
C_{4,j} &= \frac{2(\kappa_j \frac{1}{\kappa_j} - \log \kappa_j - 1)}{(\log \kappa_j)^2} \quad \text{for} \quad j = 1, 2.
\end{align*}
\]

In what follows, we derive the results in (45a) - (45c).

From \( \theta_0 \sigma_\xi^2 = \omega_\xi^2 \) in (21c) and \( \gamma_3 = -\phi_2 \theta_u \sigma_\xi^2 \) in (44d), we have \( \omega_\xi^2 = -\frac{\gamma_3}{\phi_2}, \) which is the first result in (45a). Furthermore, from (3), (4) and (13), after some calculations, it follows that:

\[
\begin{align*}
\sigma_\eta^2 &= \frac{2B_1 \omega_1^2}{1 + \theta_1^2 + \theta_2^2} + \frac{2B_2 \omega_2^2}{1 + \theta_1^2 + \theta_2^2} \quad \text{and} \\
\sigma_d^2 &= \frac{2m^2 C_{4,1} \omega_1^2 + 2m C_{4,2} \omega_2^2}{m}.
\end{align*}
\]
where
\[ B_j = \pi_1 C_{1,j} - \pi_2 C_{2,j} - \phi_2 C_{3,j} \quad \text{for} \quad j = 1, 2. \] (50)
Substituting (49) into the autocovariance functions in (44) and rearranging, we have:
\[
\begin{align*}
\gamma_0 &= 2D_1 \omega_1^2 + 2D_2 \omega_2^2 + 2 \frac{1}{m} \sigma^4 + \left[ \pi_1 \left( \frac{1}{\theta_1} + \theta_u \right) - 2 \pi_2 \right] \omega_1^2, \\
\gamma_1 &= 2E_1 \omega_1^2 + 2D_2 \omega_2^2 - 2 \frac{1}{m} \sigma^4 - \left[ \pi_2 \left( \frac{1}{\theta_1} + \theta_u \right) - (\pi_1 - \phi_2) \right] \omega_1^2, \\
\gamma_2 &= 2F_1 \omega_1^2 + 2D_2 \omega_2^2 - 2 \frac{1}{m} \sigma^4 - \left[ \phi_2 \left( \frac{1}{\theta_1} + \theta_u \right) + \pi_2 \right] \omega_1^2,
\end{align*}
\] (51a,b,c)
where \( D_j = B_j + m \pi_1 C_{1,j}, \) \( E_j = \rho_1 B_j - m \pi_2 C_{1,j}, \) \( F_j = \rho_2 B_j - m \phi_2 C_{1,j} \) for \( j = 1, 2, \) \( \rho_1 = (\theta_1 + \theta_2)/(1 + \theta_1^2 + \theta_2^2) \) and \( \rho_2 = \theta_2/(1 + \theta_1^2 + \theta_2^2). \) Hence, we have
\[
\pi_2 \gamma_0 + \pi_1 \gamma_1 = (\pi_2 + \rho_1 \pi_1) \left( 2B_1 \omega_1^2 + 2B_2 \omega_2^2 \right) + \left[ \pi_1(\pi_1 - \phi_2) - 2 \pi_2 \right] \omega_1^2,
\] (52a)
and
\[
\pi_2 \gamma_2 - \phi_2 \gamma_1 = (\rho_2 \pi_2 - \rho_1 \phi_2) \left( 2B_1 \omega_1^2 + 2B_2 \omega_2^2 \right) - \left[ \phi_2(\pi_1 - \phi_2) + \pi_2 \right] \omega_1^2.
\] (52b)
Noting that \( \rho_1 \) and \( \rho_2 \) can be expressed as in (14) (see the explanations below (14)), we have:
\[
\begin{align*}
\rho_1 &= \frac{-\pi_2 \text{var}[IV_j] + (1 + \phi_1^2 - \phi_2 \phi_1) \text{cov}[IV_j, IV_{j-1}] - \phi_1 \text{cov}[IV_j, IV_{j-2}]}{(1 + \theta_1^2 + \theta_2^2) \sigma_n^2} \\
&= \frac{\sum_{j=1}^{\infty} \left[-2 \pi_2 C_{1,j} + (1 + \phi_1^2 - \phi_2) C_{2,j} - \phi_1 C_{3,j} \right] \omega_j^2}{2B_1 \omega_1^2 + 2B_2 \omega_2^2},
\end{align*}
\] (53a)
and
\[
\begin{align*}
\rho_2 &= \frac{-\phi_2 \text{var}[IV_j] - \phi_1 \text{cov}[IV_j, IV_{j-1}] + \text{cov}[IV_j, IV_{j-2}]}{(1 + \theta_1^2 + \theta_2^2) \sigma_n^2} \\
&= \frac{\sum_{j=1}^{\infty} \left[-\phi_2 C_{1,j} - \phi_1 C_{2,j} + \phi_1 C_{3,j} \right] \omega_j^2}{2B_1 \omega_1^2 + 2B_2 \omega_2^2},
\end{align*}
\] (53b)
Substituting \( B_j \) in (50), \( \rho_1 \) and \( \rho_2 \) in (53) into (52), we have:
\[
\pi_2 \gamma_0 + \pi_1 \gamma_1 = 2 \pi_2 \sum_{j=1}^{2} \left( \pi_1 C_{1,j} - \pi_2 C_{2,j} - \phi_2 C_{3,j} \right) \omega_j^2 \\
+ \pi_1 \sum_{j=1}^{2} \left[-2 \pi_2 C_{1,j} + (1 + \phi_1^2 - \phi_2) C_{2,j} - \phi_1 C_{3,j} \right] \omega_j^2 \\
+ \pi_1 \left[ \pi_1(\pi_1 - \phi_2) - 2 \pi_2 \right] \omega_j^2
\] (54)
and
\[
\begin{align*}
\pi_2 \gamma_2 &- \phi_2 \gamma_1 = \pi_2 \sum_{j=1}^{2} \left( -\phi_2 C_{1,j} - \phi_1 C_{2,j} + \phi_1 C_{3,j} \right) \omega_j^2 \\
- \phi_2 \sum_{j=1}^{2} \left[-2 \pi_2 C_{1,j} + (1 + \phi_1^2 - \phi_2) C_{2,j} - \phi_1 C_{3,j} \right] \omega_j^2 \\
- \left[ \phi_2(\pi_1 - \phi_2) + \pi_2 \right] \omega_j^2
\] (55)
We can regard (54) and (55) as the following system of two equations for \( \omega_1^2 \) and \( \omega_2^2 \):

\[
\begin{align*}
\alpha_0 &= (\alpha_1 C_{2,1} - \alpha_2 C_{3,1}) \omega_1^2 + (\alpha_1 C_{2,2} - \alpha_2 C_{3,2}) \omega_2^2 \\
\beta_0 &= (\beta_1 C_{2,1} + \phi_1 C_{3,1}) \omega_1^2 + (\beta_1 C_{2,2} + \phi_1 C_{3,2}) \omega_2^2,
\end{align*}
\]

where \( \alpha_0, \alpha_1, \alpha_2, \beta_0 \) and \( \beta_1 \) are as given in (46). Solving (56), we have

\[
\begin{align*}
\omega_1^2 &= \frac{(\alpha_1 \beta_0 - \alpha_0 \beta_1) C_{2,2} - (\alpha_2 \beta_0 + \alpha_0 \phi_1) C_{3,2}}{(\alpha_1 \phi_1 + \alpha_2 \beta_1) C_{2,2} C_{3,1} - (\alpha_1 \phi_1 + \alpha_2 \beta_1) C_{2,1} C_{3,2}} \\
&= \frac{(1 - \kappa_1)^2 \left[ (\alpha_1 \beta_0 - \alpha_0 \beta_1) - \kappa_2 (\alpha_2 \beta_0 + \alpha_0 \phi_1) \right]}{(1 - \kappa_1)^2 (\kappa_1 - \kappa_2)(\alpha_1 \phi_1 + \alpha_2 \beta_1)},
\end{align*}
\]

and

\[
\begin{align*}
\omega_2^2 &= \frac{(\alpha_0 \beta_1 - \alpha_1 \beta_0) C_{2,1} + (\alpha_0 \phi_1 + \alpha_2 \beta_0) C_{3,1}}{(\alpha_1 \phi_1 + \alpha_2 \beta_1) C_{2,2} C_{3,1} - (\alpha_1 \phi_1 + \alpha_2 \beta_1) C_{3,2} C_{2,1}} \\
&= \frac{(1 - \kappa_2)^2 \left[ (\alpha_0 \beta_1 - \alpha_1 \beta_0) + \kappa_1 (\alpha_0 \phi_1 + \alpha_2 \beta_0) \right]}{(1 - \kappa_2)^2 (\kappa_1 - \kappa_2)(\alpha_1 \phi_1 + \alpha_2 \beta_1)}.
\end{align*}
\]

From (44e) and (21a), we have:

\[
\sigma^2 = \frac{c_{RV} - (1 - \phi_1 - \phi_2) \sigma^2}{2(1 - \phi_1 - \phi_2) m}.
\]  

Substituting \( \sigma^2 \) in (57) into \( A \) in (22), we have:

\[
2A = \frac{2c_{RV} \sigma^2}{(1 - \phi_1 - \phi_2) m \omega^2} - \frac{3\sigma^4}{m \omega^2} + 2(2m - 1) + \frac{c_{RV}^2}{(1 - \phi_1 - \phi_2)^2 m \omega^2}.
\]  

From (34), (51c) and (58), we have:

\[
\gamma_2 = 2\omega_1^2 (\rho_2 B_1 - m \phi_2 C_{4,1}) + 2\omega_2^2 (\rho_2 B_2 - m \phi_2 C_{4,2}) - 2\sigma^4 \phi_1 m
\]

\[
- \left\{ \phi_2 \left[ \frac{2\sigma^4 \sigma^2}{(1 - \phi_1 - \phi_2) m \omega^2} - \frac{3\sigma^4}{m \omega^2} + 2(2m - 1) - \frac{c_{RV}^2}{(1 - \phi_1 - \phi_2)^2 m \omega^2} \right] + \pi_2 \right\} \omega^2 = \rho_2 (2B_1 \omega_1^2 + 2B_2 \omega_2^2) - \phi_2 (2m \omega_1^2 C_{4,1} + 2m \omega_2^2 C_{4,2})
\]

\[
+ \sigma^4 \frac{\phi_1 m}{m} - \sigma^2 \left( \frac{2c_{RV} m \omega^2}{(1 - \phi_1 - \phi_2) m \omega^2} - 2\phi_2 \omega_2^2 (2m - 1) - \frac{c_{RV}^2}{(1 - \phi_1 - \phi_2)^2 m \omega^2} \right) - \pi_2 \omega_2
\]  

\[
= 2 \sum_{j=1}^2 (-2\phi_2 C_{1,j} - \phi_1 C_{2,j} + C_{3,j} - 2m \phi_2 C_{4,j}) \omega_j^2
\]

\[
+ \sigma^4 \frac{\phi_1 m}{m} - \sigma^2 \left( \frac{2c_{RV} m \omega^2}{(1 - \phi_1 - \phi_2) m \omega^2} - 2\phi_2 \omega_2^2 (2m - 1) - \frac{c_{RV}^2}{(1 - \phi_1 - \phi_2)^2 m \omega^2} \right) - \pi_2 \omega_2.
\]

Multiplying both sides in (59) by \( m/\phi_2 \) and rearranging, we have:

\[
\sigma^4 - \frac{2c_{RV}}{1 - \phi_1 - \phi_2} \sigma^2 - \frac{c_{RV}^2}{(1 - \phi_1 - \phi_2)^2} - 2\omega_2^2 m(2m - 1) - H,
\]  

where \( H \) is as given in (47). Solving the quadratic equation for \( \sigma^2 \), and by the same argument as used in (39), we have:

\[
\sigma^2 = \frac{c_{RV}}{1 - \phi_1 - \phi_2} - \frac{\sqrt{c_{RV}^2 + 2m(2m - 1)\omega^2 + H}}{(1 - \phi_1 - \phi_2)}.
\]  

and

\[
\sigma^2 = \frac{1}{2m} \sqrt{2c_{RV}^2 + 2m(2m - 1)\omega^2 + H}.
\]  

21
From (60) and (61), we have (45c) and (45d).

Finally, we summarize direct and indirect approaches for estimating the parameters in the two factor case.

**Summary of the indirect approach**

**Step 1** For a given $m$, calculate $RV_t^{*\star(m)}$.

**Step 2** Estimate the unrestricted ARMA(2, 3) model in (41) by QML estimation assuming Gaussian innovations.

**Step 3** Given the estimates of $c_{RV}^{(m)}$, $\kappa_1$, $\kappa_2$, $\delta_1^{(m)}$, $\delta_2^{(m)}$, $\delta_3^{(m)}$ and $\sigma_e^2$ obtained in Step 2, calculate the first four autocovariances of the MA process, namely, $\gamma_j^{(m)}$, $j = 0 \sim 3$ as in (43).

**Step 4** Given the estimates of $c_{RV}^{(m)}$, $\kappa_1$, $\kappa_2$ and $\gamma_j^{(m)}$, $j = 0 \sim 3$, obtained in Steps 2 and 3, estimate $\omega_e^2$, $\sigma_e^2$, $\omega_1^2$, $\omega_2^2$ and $\sigma^2$, applying the results in (45a) - (45c).

**Summary of the direct approach**

**Step 1** For a given $m$, calculate $RV_t^{*\star(m)}$.

**Step 2** Given $\kappa_1$, $\kappa_2$, $\sigma^2$, $\omega_1^2$, $\omega_2^2$, $\sigma_e^2$ and $\omega_e^2$, calculate $c_{RV}$, $\theta_1$, $\theta_2$, $\sigma_n^2$, $c_u^{(m)}$, $\theta_u^{(m)}$, $\sigma_\xi^{2(m)}$ and $\sigma_d^{2(m)}$ according to (3), (13) and (22).

**Step 3** With the $c_{RV}$, $\theta_1$, $\theta_2$, $\sigma_n^2$, $c_u^{(m)}$, $\theta_u^{(m)}$, $\sigma_\xi^{2(m)}$ and $\sigma_d^{2(m)}$ obtained in Step 2, calculate the Gaussian log-likelihood of the state space form in (40a) - (40b), for $RV_t^*$.  

**Step 4** Maximize the log-likelihood obtained in Step 3 with respect to the seven parameters, $\kappa_1$, $\kappa_2$, $\sigma^2$, $\omega_1^2$, $\omega_2^2$, $\sigma_e^2$ and $\omega_e^2$ to obtain the QML estimates.

---

*These can be obtained from the estimates of $\phi_1$ and $\phi_2$. See footnote 2.*
