- The Accelerating Rate of Change
- The New Growth Theory – Semilog scaling
- What to make of these predictions?
- Humans now control evolution
- The Value of Models

1. The singularity is not armageddon nor a dire prediction of Nostradamus!
2. But it does fortell an inevitable cataclysmic change in the world.
3. “I set the date for the Singularity — representing a profound and disruptive transformation in human capability — as 2045. The nonbiological intelligence created in that year will be one billion times more powerful than human intelligence today.” Kurzweil, p. 136
4. Changes in technology and human evolution will so profound and so rapid that it is impossible to predict what life will like after the singularity — it is beyond our “event horizon”.
5. In particular humanity, as we now know it will be obsolete — superseded by a new generation of super intelligent quasi biological androids — *andro super sapiens*.

# The Six Epochs

## The Six Epochs of Evolution

Evolution works through indirection: it creates a capability and then uses that capability to evolve the next stage.

- The Value of Models

1. Eckard Wimmer created the first artificial virus in 2002. We can clone sheep, build artificial organs, and in less than a decade humans will be creating *artificial life*.
2. A June 2006 *Scientific American* article by the “bio fab group” describes “Engineering Life: Building a Fab for Biology” “We are progressing toward first designing and modeling biological devices in computer, then ‘cutting’ them into biological form as the final step — much as silicon chips are planned, then etched.” (p. 51)
3. The result is a huge speedup in the rate of evolution: “These technologies — releasable parallel synthesis and error correction — permit us to assemble long, relatively error-free DNA constructs far more rapidly and inexpensively than has been possible to date. They can therefore constitute basis of a bio fab, and much like semiconductor chip lithography, these processes can be expected to keep steadily improving over time. That frees us to think about what we will build in the fab. (p. 48).

5. Instead, I adopt a common approach in economics, *consumer sovereignty*, and do not question the decision maker’s utility function.
6. The common feature of all the examples I presented are decision makers with *seriously distorted perceptions of reality*.

# Definition of a bad decision

1. **Definition:** A **bad decision** is a decision under uncertainty that is made by a decision maker (DM) (according to either an expected utility or non-expected utility criterion) whose subjective probability distribution that is greatly at odds relative to the objective probability distribution governing the *ex post* payoff relevant states of nature in the sense that the **loss (under the objective probability measure) from taking the decision is large.**

Further, the DM knows the decision will result in a high probability of very bad *ex post* losses, even relative to the DM's distorted subjective beliefs, but the DM does it anyway.
2. That is, a crazy decision is one that the DM refuses to change, even after learning that their view of the world is grossly incorrect and that their decision will result in large *ex ante* losses and a high probability of catastrophic *ex post* losses.
3. **Example:** A daughter of “Christian scientists” has a treatable cancer but will surely die if chemotherapy is not given immediately. The church tells the parents that it is consistent with God’s will to give their daughter chemotherapy. The parents still refuse, flee with their daughter to avoid arrest, and she soon dies of cancer.

- The Problem of "20-20 Hindsight"

1. My definition treats beliefs as if they are exogenously specified.
2. In reality, beliefs are endogenously determined, affected by endogenous *information acquisition* and *learning* decisions.
3. Much learning occurs in a social context, and we are strongly influenced by the beliefs of others around us, *particularly those we look up to and admire*.
4. Beliefs of powerful leaders of nations and corporations are affected by another important avenue: **the advice of their advisors**.
5. Advisors do not typically bear the risks associated with taking their advice.
6. In addition, there is a real danger that advice to a powerful leader will be biased: **advisors will seek the favor of the leader by providing the advice that they perceive the leader wants to hear**.

# The Role of Expert advisors

# A Bush war advisor, now a Bush war critic

Richard Perle

# Biased advice and the Iraq war decision

1. The head of the CIA, George Tenet (a Clinton appointee), advises Bush in early 2003 that there was a “slam dunk case” for the existence of weapons of mass destruction in Iraq. But contrary views of experts within the CIA were suppressed.

- The Problem of “20-20 Hindsight”

1. The head of the CIA, George Tenet (a Clinton appointee), advises Bush in early 2003 that there was a “slam dunk case” for the existence of weapons of mass destruction in Iraq. But contrary views of experts within the CIA were suppressed.
2. Dick Cheney, the Vice President, made an unprecedented number of visits to the CIA to “press the case” for the existence of weapons of mass destruction.
3. Cheney received a \$20 million departing bonus from Halliburton, the company he was President of before becoming President of the United States. Since the war started, Halliburton has received over \$20 billion in Iraq reconstruction contracts, most of which were **no bid, cost-plus contracts**.

# Scientific advice and good decisions

1. As scientists, we would like to believe that science is a purely “objective” and unbiased source of advice to leaders, and as such, scientific advice should result in better decisions.

# Conclusions

1. We have shown that the SSDI/SSI award process used by the SSA is very noisy, resulting in award error rates of over 20% and rejection error rates of over 50%
2. Most of the screening in the DI award process is done by the applicants themselves, via self-screening the application and appeal decisions, not by the SSA bureaucracy.

1. Applications for disability take place in a community/social context. Doctors', friends', and bureaucrats' knowledge of the disability program can affect an individual's decision to apply for DI.
2. Thus, the committee of experts felt that potential DI applicants were randomly selected into the “treatment group” of those eligible for the \$1 for \$2 offset.
3. Instead, in order to get an accurate assessment, *entire communities* (counties) would have to be selected for inclusion in the treatment group.
4. But since there are very large geographic variations in DI application and award rates, and in overall economic conditions in the county, large numbers of counties would have to be included in the treatment and control groups.

4. But since there are very large geographic variations in DI application and award rates, and in overall economic conditions in the county, large numbers of counties would have to be included in the treatment and control groups.
5. This means that potentially millions of people would be living in counties that were randomly selected into the treatment group of counties whose citizens are eligible for the \$1 for \$2 offset.

# A Life Cycle Model

1. The model assumes maximum possible age is 100. We solve for optimal labor supply, consumption and Social Security (pension and disability) application decision rules by backward induction from age 100 to age 21.

1. Recall, the IRR is the  $r$  that solves

$$(1) \quad 0 = \sum_{t=0}^T \exp\{-a_t r / 365\} c_t,$$

where  $c_t$  is the cash inflow (if positive) or outflow (if negative), and  $a_t$  is the number of days after the initial purchase of the vehicle that the  $t^{\text{th}}$  cash flow occurred.

Improving Car Rental Profits

2.1 Analyzing Rentals

- Rental Contracts
- Typical Rental Histories
- Comments

1. Recall, the IRR is the  $r$  that solves

$$(1) \quad 0 = \sum_{t=0}^T \exp\{-a_t r / 365\} c_t,$$

where  $c_t$  is the cash inflow (if positive) or outflow (if negative), and  $a_t$  is the number of days after the initial purchase of the vehicle that the  $t^{\text{th}}$  cash flow occurred.

2. Thus,  $c_0 < 0$  and  $a_0 = 0$  represent the initial purchase of the car,  $a_T$  is the *service life* and  $c_T$  is the resale price the company receives from selling the car in the used car market, or at an auction.

- Comments

1. Recall, the IRR is the  $r$  that solves

$$(1) \quad 0 = \sum_{t=0}^T \exp\{-a_t r / 365\} c_t,$$

where  $c_t$  is the cash inflow (if positive) or outflow (if negative), and  $a_t$  is the number of days after the initial purchase of the vehicle that the  $t^{\text{th}}$  cash flow occurred.

2. Thus,  $c_0 < 0$  and  $a_0 = 0$  represent the initial purchase of the car,  $a_T$  is the *service life* and  $c_T$  is the resale price the company receives from selling the car in the used car market, or at an auction.
3. We see that for each of the cars illustrated in figure 1, the realized rates of return are extraordinarily high. *These high returns are not atypical.*

- Economists are accustomed to “marginal arguments” for optimal decision making.
- The rental company must select a “portfolio” of vehicles for the lots in each of its rental locations.
- Similar to standard portfolio analysis in finance, at an optimal allocation the company should be getting roughly the same expected “risk adjusted return” from an investment of \$ $X$  in car type  $\tau_1$  as it does for an equivalent investment in car type  $\tau_2$ .
- Otherwise if there is one type of car that has a higher return per dollar invested, then the firm would be better off investing the marginal dollar in the car type that yields the highest possible returns.
- Our analysis has revealed that of the three car types we have analyzed, the compact has the *highest rate of return* even though it has the lowest *discounted value of profits per car*.

- Clearly some customers will want to rent compacts, others will prefer RVs and others will prefer to have luxury vehicles.
- If the company happens to be “stocked out” of a particular customer's most preferred type of vehicle, having a portfolio with sufficiently close substitutes may enable the company to keep that customer, as opposed to the customer walking down to the next rental company window to see if a competitor has their preferred vehicle in stock and ready to rent.

- Let  $\bar{P}_j$  be the new purchase price of car type  $j$ .
- Then we can formulate the overall **optimal rental operations problem** as the following programming problem

$$(11) \max_{\mathcal{R}} \max_{\{N_{ij}\}} \sum_{i=1}^N \sum_{j=1}^J N_{ij} [V_{ij}(\mathcal{R}) - \bar{P}_j] \text{ subject to: } \sum_{j=1}^J N_{ij} \leq M_i$$

- Nested within this problem is the regenerative optimal stopping problem, that we have solved in this paper, that delivers the value function  $V_{ij}(\mathcal{R})$  for all car types at all of the firm's rental locations.
